FOREWORD

The 1960's were frequently cited as containing perhaps the most rapid and pervasive demographic and social change our country has witnessed. Unfortunately, there have been few opportunities to monitor these events. The 1970 Censuses of Population and Housing has provided our first chance to do so in any detail, both from printed and taped data. For the user, however, the Census carries with it certain difficulties in terms of convenience of access and the volume of material available.

This publication, Part 2 of a three-part series, attempts to improve availability while at the same time providing derivative population analyses not directly obtainable from Census sources. It represents a joining of interests on the part of the Tennessee State Planning Commission and the Center for Business and Economic Research (CBER). Projects such as this are a part of CBER's research and public service mission of supporting the information needs of the University, Tennessee State and local governments, and the State's business community. The State Planning Commission not only helped bring about the release of the data by sharing printing expenses, but also sharpened the focus on planning problems by suggesting alternate data items and by reviewing the overall design and timing of the publication.

The three-part series of reports, each part with its own special emphasis, is not a voluminous collection and reformation of 1970 Census data. It is more a summary presentation of basic and derived data emphasizing changes in selected population and housing data over three census points. It should serve as a timely basic data resource for research and planning from the local to the State level. What is the voting age potential? Do we have a problem of providing services for an aging population or of meeting the needs of a younger population? What is the complexion of housing quality now as opposed to 20 years ago? How does recent migration compare with that of other decades, and have age-sex patterns persisted? What is the potential for population increase in coming years? What is the structure of our population? In what manner have the labor force and income distributions been altered over time? These are the types of questions toward which the data are directed. Included are items designed to provide a sketch, an overview, of change for Tennessee, its subregions and counties. This report, and the series as a whole, provides a healthy data base both for further research work and for planning public and private investment policy.

Tilden Curry, Acting Executive Director
State Planning Commission
State of Tennessee

PREFACE

The three-part "profile" series has grown from a concern to have close at hand summary indicators charting the direction of change in population and housing in Tennessee counties over the last two decades. It was originally designed as an informal guide to demographic change in each county: a collection of unpublished tables to serve as background and basic orientation material in demographic and economic research at The University of Tennessee. As the data were being compiled and as new data items were included, the possibility for more general application of the series to related research outside UT became apparent.

Still there is no intention of providing an exhaustive social accounts atlas. The attempt is rather to collect in one place summary data from consecutive censuses that will identify problems or highlight the changing character of the State and each county. And the concern might range from quality of housing to family dissolution or migration. Comparabality across the census data points has been maximized but of course is not insured for all items. Close attention must be given to the notes applying to each table.

Part 2 presents population and percentages by age and sex, a population pyramid, and preliminary migration estimates by age and sex for 1960-1970 by county. Part 1, released in April 1971, contained (1) two summary tables containing general ranking and change data for the State and counties and (2) a third table for each county showing selected population and housing data. Part 3 will focus upon education, income and employment. Since 1970 data entries are from the 1970 Censuses of Population and Housing, the timing of release for the three volumes corresponds with availability of the first, second and fourth count computer tape files, respectively.

A special note of appreciation is due Tilden Curry and Niles Schoening of the Tennessee State Planning Commission and E. Jane Hazlewood of the Tennessee Office of Comprehensive Health Planning for review of both specific content and general structure of the series. Additional thanks go to Martin Hatzadourian for his efforts in computer programming.

INTRODUCTION AND NOTES

The two "tables" shown for each area in the following pages present somewhat of a chronicle of population change for the decade of the 1960's. The 1960 population pyramid represents the age-sex structure of the population at the beginning of the period, the 1970 pyramid indicates the structure at the end of the period, and the accompanying table of net migration presents data on the major factor responsible for differences in the two pyramids. The level of births during the decade is reflected in the bottom two lines of the 1970 pyramid.

The purpose of the population pyramid is to sketch graphically a "picture" of an area's population at some point in time. It is merely two bar charts placed back-to-back; one contains the distribution of females by age and the other shows the male distribution by age. The 1960 and 1970 pyramids both have been included here for comparative purposes. In such proximity changes in the basic composition of an area's population may be identified visually with little difficulty. In fact, the alteration in the shape of the pyramids in only ten years is rather striking for most areas. Some of the counties showing the greatest amount of change are Anderson, Bledsoe, Putnam, Rutherford and Sumner Counties. The Middle Tennessee and Memphis-Delta Planning Regions show similar tendencies. Most areas underwent some change through the normal aging process during the decade. Also there is a nearly universal "pinching" of the structure in the two youngest age categories due to the reduced number of births during both the 1960-1964 and 1965-1969 periods.

With little more difficulty, the structure of counties or regions may be compared with each other as well. Contrast, for instance, the pyramids for Bradley, Crockett, Fayette, Montgomery and Putnam Counties. Each has its own unique configuration. The problems facing areas with such divergent populations and underlying population dynamics are certain to demand individual treatment. Without reference to the migration table, for example, it may be concluded that Fayette County is hit very hard by outmigration in the 20-29 age category but continues to have a high fertility level. It is a largely rural and predominantly nonwhite county. Bradley and Hamblen Counties have nearly perfect symmetrical pyramids. They have experienced net inmigration uniformly across the age spectrum, have lower fertility levels, are more urban and are largely white counties. Programs that meet with success in these areas should be expected to have little impact in Fayette County.

The pyramids serve a secondary function of providing a check on data quality.

Some possible difficulty is evident, for example, from even a surface comparison of consecutive age groups. With completely valid and

reliable census counts, adjacent age categories might be expected to have an identical population count occasionally or perhaps more frequently for very small areas. However, this situation is found in 20 of Tennessee's 95 counties and occurs with 29 different pairs of consecutive age groups. In Maury County the matching counts occur in age groups containing nearly 1,300 persons and in Cheatham County is found in three sequential age groups. It is somewhat comforting to find that the counts for single-year age groups making up the five-year categories involved do not contain this difficulty. However, the problem remains one which reflects poorly on data quality and must be dealt with in evaluation of local census data.

During the last decade Tennessee's level of total net migration was approximately -45,000 in contrast with the -272,000 of the 1950's. A tendency toward a net migration of zero may be observed in many counties across the State. One explanation, of course, is that persons wanting to leave did so during the 1950's; and the reduced fertility levels of the 1960's and late 1950's did not replace them. As a result, the late 1960's and early 1970's should bring a reduction in outmigration. Provisional estimates of migration for April 1970-July 1971 seem to bear this out, with a net inmigration of 10,000 to 15,000 persons.

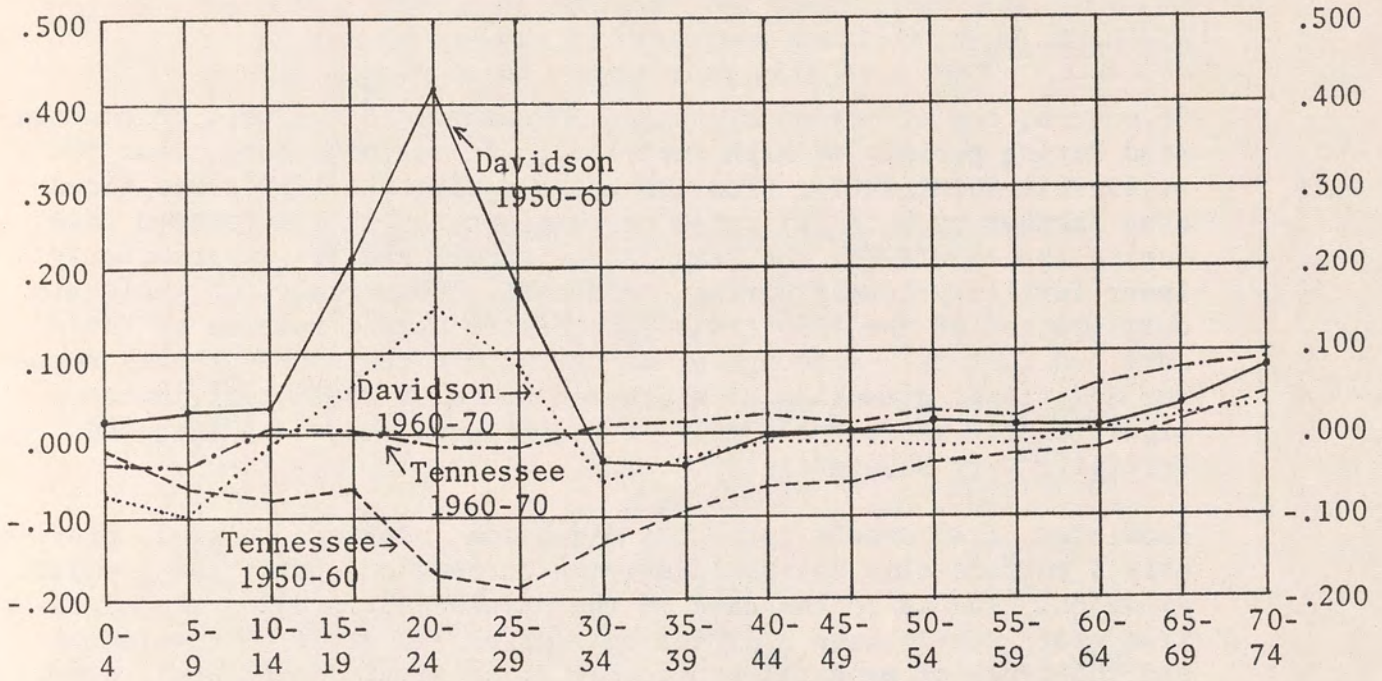

One of the obvious conclusions from the analysis by age, however, is that the age patterns of the 1950's have persisted. Rates of net migration by age are plotted in Figure 1 for Tennessee and Davidson, Knox and Houston Counties during the 1950-1960 and 1960-1970 decades.

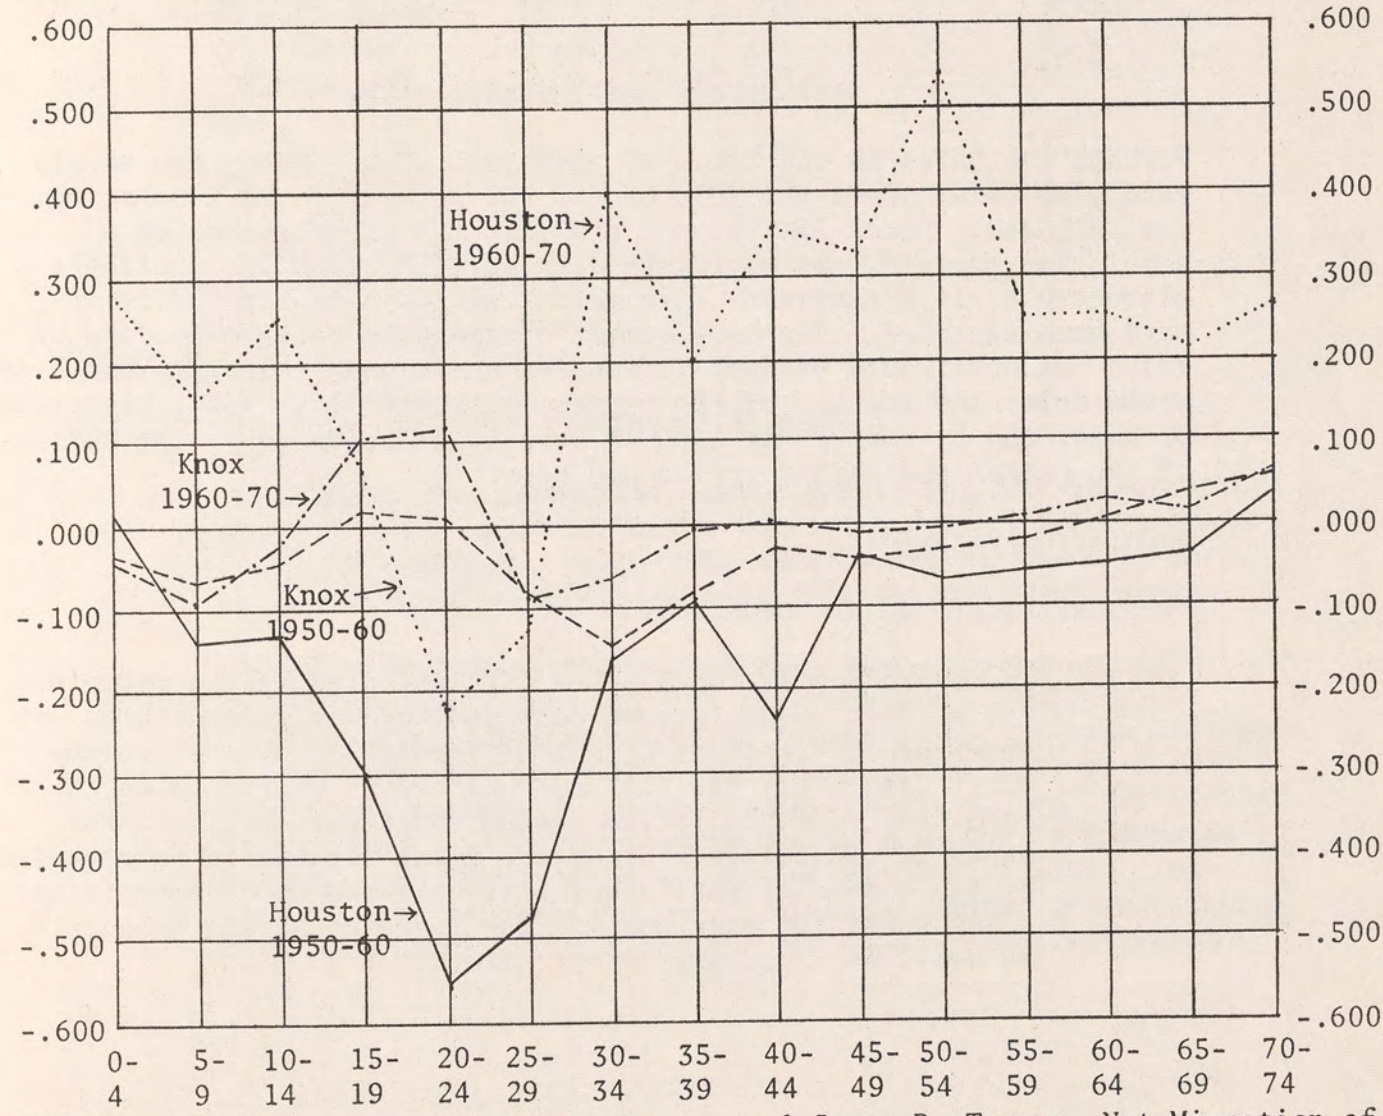

Despite a vertical shift in position and some minor variations in the early age categories, the curves for 1960-1970 have the same configuration as their counterparts for the 1950-1960 period. Houston County has been included in Figure 1 for comparative purposes. It was selected on the basis of its size, relatively high total rate of outmigration for 1950-1960 and high rate of inmigration for 1960-1970. Again it is apparent that the age curve of the 1950's has continued even though the level of migration shifted dramatically and total migration had an opposite sign in the two decades.

An important by-product of the redistribution of persons through migration is the simultaneous redistribution of natural change (births minus deaths) due to the age structure of the migrant population. Taeuber found that regions experiencing outmigration during the 1960's were characterized by significant declines in the number of children.[1] The 1960-1970 curves for Knox County and Tennessee in Figure 1 point out rather clearly why this might be the case. The upswing to positive migration rates for the 15-19 and 20-24 age categories in Knox and Davidson Counties, for example, carries with it a jog upward in the curve for the 0-4 ages. In contrast, the Tennessee curve does not rise for the 15-19 and 20-24 groups or the

Figure 1

Comparison of 1950-1960 and 1960-1970 Net Migration Rates by Age:
State of Tennessee, Davidson, Knox and Houston Counties

SOURCE: 1950-60 rates - Gladys K. Bowles and James D. Tarver, Net Migration of the Population, 1950-60, by Age, Sex, and Color, I, Pt.4, Washington, DC, 1965. All ages were not included because of differences in number of years in terminal category.

0-4 category.

Of course, the effect of migration on natural change will be accentuated during periods of high fertility. It follows, then, that the negligible outmigration from Tennessee during the 1960's was aided even farther by both (1) rates of outmigration closer to zero than during the 1950's for the fertile age groups and (2) substantially lower fertility levels during the decade. Conversely the wholesale outmigration of the 1950's was exaggerated by the reverse of these same two factors. Although it is not within the scope of this report, the additional dimension of migration by color would contribute significantly since the total migration level, rates by age, and fertility vary substantially.

Knowledge of an area's total net migration, although helpful, provides only a surface clue to the underlying current and potential population dynamics. And as in the case of the population pyramid, the migration profile will have a direct bearing on the style of government and the types of programs applicable to an area. An economic development plan fashioned for an area with the Tennessee migration pattern would have little relevance for an area with the Davidson County trend.

Methodology and Interpretation

Perhaps the dates in the title of this part of the monograph should read 1960-1970. Data for 1950 or for the decade of the 1950's are not included. Space limitations prohibit the presentation of a population pyramid, and migration data for 1950-1960 are available elsewhere.[2] It has already been noted that data by race or color have been excluded. The development of adequate background data by color not only would produce figures of questionable quality but also would delay the release of the report substantially. Total migration by color and by county for 1960-1970 has been released by the Bureau of the Census and is not reproduced here.[3]

Population Pyramids

Two qualifications are necessary:

1. The basic population figures for 1970 used in the pyramids and as part of background data for the migration tables are from the 1970 Federal Census of Population printed volume PC(1)-B44. They are the same numbers as contained on the 1970 Census of Population Second Count magnetic computer tapes for Tennessee. Since the final figures to be released by the Bureau of the Census will be based upon differential adjustments for each county, any revision of the numbers by us would be arbitrary and premature.

2. The following table contains the uncorrected and corrected total population for 13 Tennessee counties as an indication of the magnitude of change that will be a part of the final figures by age and sex.[4]

UNCORRECTED AND FINAL TOTAL POPULATION COUNTS FOR REVISED TENNESSEE COUNTIES: APRIL 1, 1970

Area	Uncorrected Total Population	Corrected Total Population
Tennessee	3,923,687	3,924,927
Carter County	42,575	43,259
Davidson County	448,003	447,877
Franklin County	27,244	27,289
Hawkins County	33,726	33,757
Henderson County	17,291	17,360
Houston County	5,845	5,853
Lake County	7,896	8,091
Madison County	65,727	65,774
Maury County	43,376	44,028
Shelby County	722,014	722,111
Sumner County	56,106	56,284
White County	17,088	16,355
Williamson County	34,330	34,423

Migration

A number of points require clarification here:

1. The numbers of age-specific net migrants and the corresponding rates were developed with the forward survival ratio procedure using 1959-1961 Tennessee life table survival rates.[5] They should be considered provisional from several standpoints.

   First, it has been observed already that uncorrected 1970 population figures by age and sex were used. Second, the numbers of migrants were forced to preliminary totals developed by the Bureau of the Census according to residual or vital statistics methods.[6] In the establishment of their estimates of total migration, the Census Bureau used the 1970 Advance Report population counts and estimated natural change for each county for 1969 and the first three months of 1970 from birth and death figures of 1967 and 1968. Final estimates of

migration by age must be based upon control totals that do not contain these two limitations. Third, until development of a 1960-1970 series of estimates comparable to the 1950-1960 Bowles-Tarver volumes (see reference 2), the figures contained here should serve as interim values and should not vary significantly from any such final releases. If scheduling follows that of the 1950-1960 volumes, the 1960-1970 series will not be available until mid-1975.

2. The adjustment of migration estimates by age developed by any of the survival ratio techniques to a total developed by the vital statistics method has been found to produce superior estimates by age.[7] As a result, the county migration values for each age-sex category have been forced in two directions. First, the numbers for each county were forced to the Census Bureau control totals for the counties through a plus-minus adjustment procedure. Then the total for each age-sex category for counties was forced to the Tennessee total for corresponding ages using the same adjustment techniques. The process was reiterated until no further change occurred. As a result of the adjustments, and since rounding occurs on computer output, the numbers for age-sex categories may not add precisely to the total for the counties or for a particular State age category.

   Calculations for State Planning Regions were carried out independently from counties, with the same forcing procedures as described for counties. Moreover, county values will not accumulate to regional totals. Although the nonadditive quality may cause some inconvenience, better estimates of migration for both regions and counties result from independent derivation and a minimum of intermediate alterations.

   After all adjustments, the migration rates were computed using the "expected" population at the end of the decade (assuming no migration) as the denominator.[8] The use of surviving population as a base helps neutralize some of the bias in the forward formula and results in more of a probability type statement for use later in population projection work.

3. The use of the forward formula contributes some error by understating outmigration from areas experiencing net outmigration and also by understating inmigration for areas with net migration. Hamilton has concluded also that if most of the migration activity occurred early in the decade, as it apparently did in Tennessee during the 1960's, the reverse formula should be used.[9] Tarver has indicated, however, that the amount of bias to the forward and reverse procedures is insignificant and should not be considered except in the older age categories.[10]

This tendency was found in Tennessee for the 85-and-over age category using life table survival rates and the expected 1970 population as the basis for calculating migration rates. Improved rates of migration were obtained by substituting 1950-1960 census survival ratios in the forward formula for that age group. The selection has little bearing on the resulting numbers of migrants, however. The number of migrants in that age category is sufficiently small that survival factors of varying magnitude have only a trivial impact upon the total migration level for the area.

4. With the exception of the 85-and-over group, survival rates were used as derived from the 1959-1961 Tennessee life table. The long-standing dialog on the relative advantages and disadvantages of using census survival ratios (CSR) as opposed to life table survival rates (LTSR) is inconclusive at this juncture. The sole advantage of the census survival ratio is that it incorporates corrections for differences in the completeness of enumeration and misstatement of age between censuses. The disadvantages are (1) that assumptions must be made equating U.S. and local area census quality, levels of mortality, the percentage of the population that is native, and intercensal migration, (2) that CSR's are extremely difficult to develop accurately,[11] and (3) that even granting that ratios of satisfactory quality could be produced, there will be a significant delay in their release by the Bureau of the Census.

   The use of LTSR's to derive provisional migration estimates follows from several considerations. First, at present the only CSR's available are those based on the 1950-1960 period. There is literally no justification for assuming that these ratios are applicable to the 1960-1970 decade. Second, despite Census Bureau claims, there is currently no conclusive evidence that the 1970 Census represents either an improvement or a degeneration in census completeness and misstatement of age. Some differences might be expected in areas covered by mail for the first time in 1970. For Tennessee that would include the Memphis and Nashville areas. In the absence of significant differences in census quality, however, the primary advantage of the CSR is lost.

   Third, the assumptions underlying the CSR are uncomfortable at best. For example, there has been no evaluation of census quality at a local (county or state) level comparing it to the total U.S. Further, Price has identified differences in U.S. and state mortality levels as a significant source of error in the use of the CSR.[12] Although Zachariah subsequently concluded that the error might be less than indicated by Price,[13] the use of LTSR's developed for the local area avoids this difficulty altogether.

Fourth, Hamilton presents an excellent summary tracing of the issue of the CSR versus the LTSR since the outset of work in this area during the 1930's. It is obvious from his review that most evaluation work was performed during the 1950's or earlier. At best the evaluations have utilized the 1950 and 1960 censuses and attempted to compensate for the large errors in some age categories in 1950.[14] It is doubtful that the difficulties prompting the development of the CSR will be found to a similar degree in subsequent pairs of censuses.

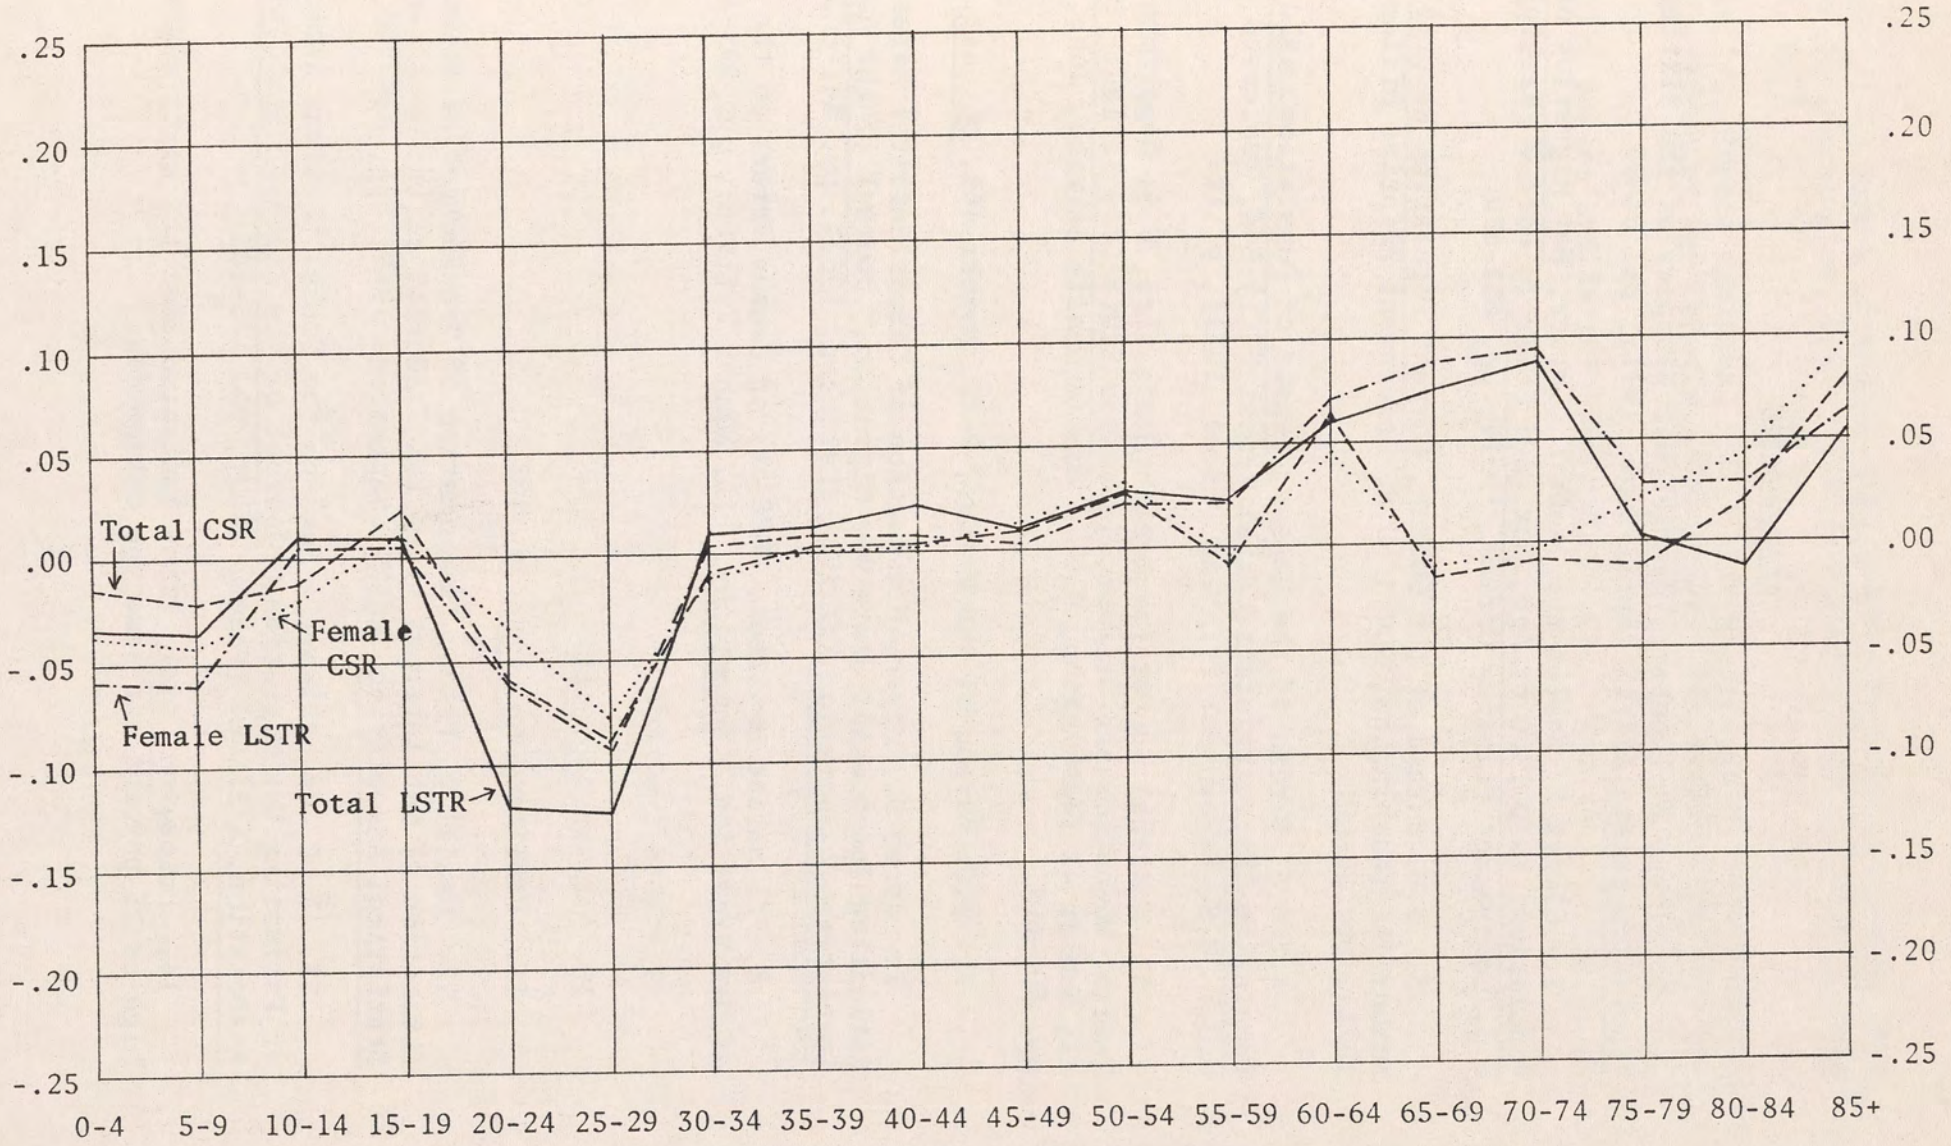

Fifth, Hamilton repeatedly applies one criterion as justification for the CSR. He has translated the under-enumeration and age misstatement problems into a concern for producing the smoothest curve when net migration rates are plotted by age. Figure 2 contains plots of 1960-1970 rates produced by the 1950-1960 CSR's[15] and the 1959-1961 LTSR's. Although the differences in the curves are not great, it must be concluded from plots of Tennessee and its counties that the LTSR curves (1) have a smaller range of fluctuation from high to low and (2) present a smoother and more regular curve. A similar tendency is found when numbers of migrants are plotted rather than rates. Following Hamilton's lead, this is perhaps the strongest recommendation for LTSR's as a means of developing provisional migration estimates.

Sixth, a method proposed by Hamilton for producing migration estimates by age through the vital statistics method avoids many of these concerns.[16] However, at the county level it is extremely cumbersome, it is demanding in terms of the data required, and as a result is not timely. In addition he concludes that the method frequently can lead to substantial error.

5. Finally, the resulting numbers and rates represent total net migration from 1960 to 1970, including military, student and international migration. The results are as nearly comparable as possible with data presented by Bowles and Tarver for the 1950-1960 period.[17] A final caution on comparability is that the Bowles-Tarver rates are per 100 survivors whereas those contained here do not incorporate the multiplication by 100.

Figure 2

Rates of 1960-1970 Net Migration for Tennessee by Age
from 1959-1961 Life Table Survival Rates and 1950-1960 Census Survival Ratios*

*NOTE - The 85 and over LTSR rate was developed using the 1950-1960 CSR rather than the 1959-1961 LTSR.
