FOREWORD

A wide variety of planning efforts in such areas as health, highways, education, and economic development depend on information about the future size and composition of the population and labor force.

The following projections of population and labor force were prepared as part of a study of manpower requirements in higher education, but because of their potential value to other persons interested in population and labor force projections, we decided to publish them separately before the completion of the entire study.

The potential applications of detailed demographic and labor force baseline data are obvious in land-use planning, development of expressway systems, and provision of recreational facilities, adequate health care, and comprehensive educational services. Federal requirements for basic population and labor force data in planning grant applications are well recognized. Information for these purposes is provided in this monograph.

The projection work was supported in part by the Tennessee Higher Education Commission as a portion of a larger investigation of future college and university-trained manpower requirements. The projections (1) began with an appraisal of recent trends and the current status of relevant population and labor force data, (2) went on to construct in some detail three series of assumptions about the future of the three population change factors, and (3) applied the assumptions to project population and labor force in such detail as is feasible. The projection technique is based on a detailed analysis of historical trends in fertility, mortality, and migration and provides detailed alternative projections.

Figures of this type are *projections*, or the numerical consequences of the assumptions selected. The numbers are conditional upon the assumptions being fulfilled. The user, however, typically wants a *prediction* of what actually will happen in the future. The bridge between the two points of view is the choice among assumptions. Insofar as these are realistic, the projections will indeed predict the future. The key, then, to use of the projections presented here is to pay close attention to the assumptions underlying them. It is the responsibility of the user to choose among assumptions on the basis of the use for which the figures are to be applied and on his knowledge of a particular subject. It is not a matter of merely selecting a future level of population. That may be done in the absence of any analysis or projections whatsoever.

In one sense, it is desirable that the projections be in error. Projections are developed to aid other research efforts but also are intended as background for program planning. One reason why projections may later be found to be poor predictions is that both public and private planning

agencies, if displeased with the projected course of events, devise policies and programs to alter them. The projections shown here have been designed for just such application.

CHAPTER 1

INTRODUCTION AND REVIEW OF PROJECTION RESULTS

In a number of program areas, the point of departure for an informed planning process is a realistic and detailed series of population and labor force projections. Presented in this volume are (1) projections of population by age and sex to 1990 for Tennessee, its nine Planning and Development Regions,¹ and counties, (2) projections of total population to 2000 for the same areas, (3) a series of labor force projections consistent with the projected levels of population, and (4) as much of the detailed analysis underlying the projections as is practical. Projections by color or race of the population were not developed due to the difficulties involved in obtaining adequate background data.

General Methodology

The population projections were developed through use of the component model. Although the method proceeds on an age-specific basis, it operates from the basic premise that:

$$P_{iT+1} = P_{iT} + \sum_{j=1}^n B_{ij} - \sum_{j=1}^n D_{ij} + \sum_{j=1}^n MI_{ij} - \sum_{j=1}^n MO_{ij}$$

where:

i	=	area i,
j	=	a particular year between 1 and n,
T	=	time one,
T+1	=	a later point in time,
n	=	number of years elapsed between times T and T+1,
P	=	total population,
B	=	annual numbers of livebirths,
D	=	annual numbers of deaths,
MI	=	immigration to area i, and
MO	=	outmigration from area i.

¹See Appendix A for a complete listing of counties in Tennessee Planning and Development Regions.

Although other projection techniques are less complex and may be completed with less time, effort, and financial commitment, they all possess serious fundamental limitations. For example, any of the apportionment or ratio procedures presupposes the availability of reliable population projections or of related series for political or geographic areas of which the state or local area is a part. A more critical shortcoming of projections by alternate techniques is that they do not permit the level of detail (for example, projections by age and sex) inherent in the component procedure. In addition, their applications as a planning tool are far more limited due to the absence of specific assumptions and the resulting lack of flexibility. As an illustration, variations in the assumed future pattern of migration, fertility, or mortality and the resulting impact upon population trends may be introduced within the component framework but may not be incorporated conveniently into other methods. This restriction imposes rather severe constraints upon the utility of other techniques in constructing alternate planning strategies.

The operation of the component procedure is illustrated in Appendix B. Initially, detailed assumptions concerning the future direction of each of the three components of population change--fertility, mortality, and net migration are established independently. Details of the steps involved are presented in subsequent chapters, one devoted to each of the three variables. On the basis of historical trends and current developments, age-and-sex-specific rates are derived for each area and time period. Here a series has been constructed for the fertility and migration components representing high or expansive conditions, medium or likely conditions, and low or unfavorable conditions. In the case of mortality,

only one series of projections has been derived. As a result, there are nine possible combinations of high, medium, and low assumptions for the three components of change.

The illustrative projection of male population presented in Appendix B uses the medium assumption series for all three components and indicates their operation in the projection model. Although the assumptions for each of the three components are set independently, they are allowed to interact later just as they do in the actual population change process. It may be observed, for example, that in the component projection model, women who move into the state are exposed to the risk of childbearing just as are those who continued to reside here from an earlier date. Similarly, women who have died during a period or have left the state are removed from risk of childbearing.

Assumptions

From among the possible combinations of assumptions for the three components, three have been utilized to develop a range of projections:

Series A - High fertility, high net migration, medium mortality.

Series B - Medium fertility, medium net migration, medium mortality.

Series C - Low fertility, low net migration, medium mortality.

Although the Series B assumptions represent a likely course of events, the three levels must be interpreted as a range of events within which the actual population should be expected to fall. The selection of a series of projections must be predicated upon several criteria. First the projections are here developed in 1972 based upon the 1970 Census of Population results released to date and preliminary vital events data

for recent years. In the 1970's, population estimates developed on a current basis each year will include up-to-date data that are not now available. These later materials may indicate that the trends for one or more of the components have gone in a direction not previously foreseen, and that the assumptions of the high or low series are more realistic than the medium.

Secondly, population trends both affect and in turn are affected by changes in economic, military, and educational conditions. For instance the phasing out of a military installation may have considerable impact upon the vital events (births and deaths), net migration, and consequently the age structure of an area. Considerations such as these are particularly important where projections for small areas are involved. The implications are that the choice of a series of population figures must be based in part on an intimate working acquaintance with conditions peculiar to the area under consideration.

Thirdly, the particular application intended for the numbers must be taken into account as well. That is not to say that a series may be chosen to prove a point or support a predetermined conclusion. Rather, for a specific use it may be appropriate to apply a projection that allows for more or less growth than is expected to occur. For example, adequate planning for telephone service in a given area should include the provision for a "cushion." In this case it would be fitting to allow for more demand rather than too little and later have to make emergency reallocations of personnel and equipment.

Projections Beyond 1990

The abilities of any projection technique are being taxed when providing age and sex detail for small areas to 1990. Consequently, only projections of total population are included to the year 2000.² All of the figures for any year must be interpreted as projections under a specified framework of assumptions. They are in no sense intended as predictions. If the assumptions underlying a series are violated, and if one of the remaining series is not based upon assumptions that more nearly reflect developing conditions, then the projections must be considered invalid and subject to revision. The derivation of a range of projections reduces the likelihood of this occurring.

Two features of the projections require clarification before discussion of the figures. First, the projections should be treated as provisional from three standpoints: (1) The projections use the 1970 Census of Population, adjusted to a state total of 3,926,018 persons, as their base.³ The adjustment includes revisions in total population for Carter, Davidson, Franklin, Hamilton, Hawkins, Henderson, Houston, Lake, Madison, Maury, Obion, Shelby, Sumner, White, and Williamson Counties. The age and sex categories within these counties were adjusted proportionally to the new totals and revised regional and state populations were prepared by summations of adjusted county figures. The resulting base populations will

²Projections containing age and sex detail for counties, regions, and the state are available from the Tennessee Higher Education Commission or The University of Tennessee Center for Business and Economic Research.

³May 26, 1972, unpublished memorandum from the Bureau of the Census to participants of the Federal-State Cooperative Program for Local Population Estimates.

not agree with 1970 Census results published to date by the Bureau of the Census; (2) as a function of selected basic analysis data being preliminary, the derivative population projections must carry the same qualification. For example, the life tables developed for 1970 may contain slight one-year fluctuations that would not be present in census-centered tables similar to the 1959-1961 analysis. Data simply were not available during the mortality analysis to permit three years of observations. The net effect upon the projections would be inconsequential but the numbers would vary slightly. (3) Similarly, additional population projections will be made later in 1972 which exercise a "feedback" option, allowing independently developed employment projections to affect the migration component. However, as indicated in the discussion of this feature in Chapter 4, the changes from the projections presented in this work will be minimal.

The second item in the projections needing clarification is the lack of agreement between projections for counties and regions. Projected values for counties have been adjusted to agree with comparable projected figures for Tennessee, except for rounding. Regional projections also have been forced to agree with the state figures, with slight differences due to rounding after adjustment. Totals for the counties will not match completely with regional numbers. County and regional projections were developed independently and were separately adjusted to the state projections. Although this may cause minor inconvenience, superior county projections result from not subjecting them to a further series of forced adjustments. The unique county patterns have been partially suppressed

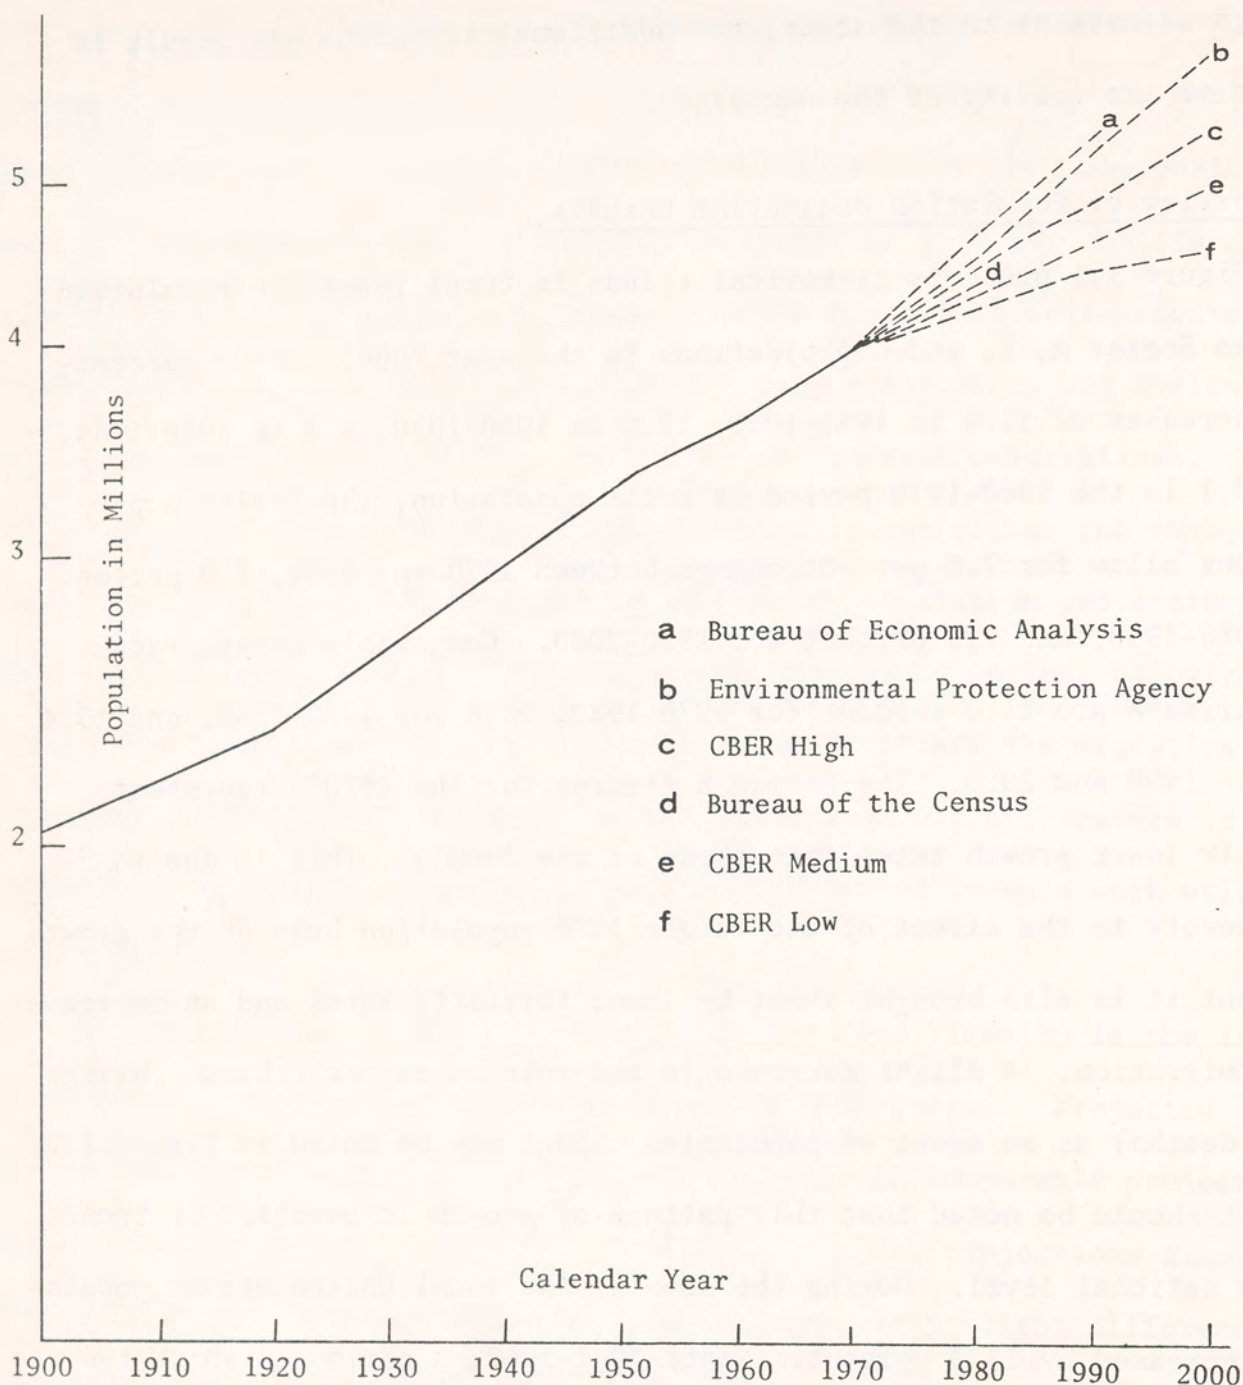

through adjustment to the state, and additional revisions may result in damage to the quality of the numbers.

An Overview of Population Projection Results

Figure 1.1 presents historical trends in total Tennessee population and the Series A, B, and C projections to the year 2000. After percentage increases of 11.4 in 1930-1940, 12.9 in 1940-1950, 8.4 in 1950-1960, and 10.1 in the 1960-1970 period in total population, the Series B projections allow for 7.6 percent change between 1970 and 1980, 7.9 percent for 1980-1990, and 7.0 percent for 1990-2000. Comparable growth rates for Series A are 11.0 percent for 1970-1980, 10.8 for 1980-1990, and 10.4 between 1990 and 2000. The Series B figures for the 1970's represent slightly lower growth rates than those of the 1960's. This is due in part merely to the effect of the larger 1970 population base on the growth rate but it is also brought about by lower fertility rates and an increase in outmigration. A slight decrease in the role of natural change (births minus deaths) as an agent of population change may be noted in Figure 1.2.

It should be noted that this pattern of growth is parallel to trends at the national level. During the 1960's, the total United States population increased by 13.3 percent. Since 1961-1962, a period in which the population growth rate was approximately 1.55, the annual rate of increase for the United States has dropped almost without exception each year to a low of 0.93 between March of 1971 and March, 1972. If this rate were to continue to 1980, it would result in a 10-year growth rate for the United States of approximately 9.7 percent. And if the United States-Tennessee ratio of the 1960's were applicable to the 1970's, the comparable Tennessee

rate of growth for the 1970-1980 period would be about 7.4 percent and would result in a 1980 population of 4,215,200 persons. This is just slightly below the Series B parameters of 7.6 percent growth and a 1980 population of 4,224,300 persons.

In the Series B projections shown in Table 1.1, rates of population change for geographic regions of the state during the next ten years range from an increase of 13.3 percent for Mid-Cumberland (Region 5) to 0.6 percent in the Upper Cumberland area (Region 4). Although the ranking of regions by population size does not change from 1970 to 2000, the differentials among regions become more pronounced. Region 5 comprises an increasing share of the state population, moving from 20.2 percent in 1970 to 23.7 percent in 2000. Similarly, Region 9 increases its share from 20.2 percent to 22.2 percent of the state. All other regions decline in their respective shares of the total Tennessee population. Table 1.2 identifies the origins of the relative growth rates for regions. The largest total increases in population were registered by Regions 5 and 9. The only region in which immigration occurred during the 1970-1980 decade was Region 5. Region 9 attained its growth through disproportionately high natural increase, largely as a result of higher nonwhite fertility levels in the area. Significant reductions of the population took place in Regions 2, 3, and 9 through outmigration.

A general idea of the changes projected in the age-sex structure of the population is indicated in population pyramids in Figure 1.3. The purpose of the population pyramid is to sketch graphically a "picture" of the population in an area at some point in time. The pyramid merely

a horizontal restriction or "pinching" of the pyramid begins to show in 1980 and is much more evident in the pyramid for 2000. That is, the structure of the pyramid is straighter vertically than in 1970. This results from both a "thickening" at the top and a restriction at the bottom of the pyramid, or a relative increase in the older population and a reduction in younger age categories.

Trends for four broad age groups are of particular interest. First, it is important to note that the percentage of the population in the 60

FIGURE 1.3
POPULATION PYRAMIDS,
STATE OF TENNESSEE: 1970, 1980, AND 2000

SOURCE: The University of Tennessee Center for Business and Economic Research.

and over age group will increase from 14.2 percent in 1970 to 16.0 in 1980 and 16.9 percent in 2000. Although the change in proportion of the population is larger between 1970 and 1980 than for the 1980-2000 period, the numerical change in population in both periods is substantial. Population in that age group will increase from 556,860 in 1970 to 673,605 in 1980 and 826,620 in 2000. The implications for growing demands on programs for the aging and sustained markets for the retirement industries are obvious.

A second point is that the working-age population (ages 15-64) will increase from 60.24 percent of the population in 1970 to 63.50 percent in 1980, and will be at that same level (63.36 percent) in 2000 after a decline to 61.61 percent in 1990. However, the number of persons in those ages will continue to increase despite the temporary 1990 drop in percentage of the total population..

Thirdly, a similar but more pronounced drop in percentage of the total population in 1990 may be observed for the ages 15-24, which category will provide students for Tennessee's higher education institutions, community colleges, and vocational training institutes. The percentage of the population in these ages declines slightly from 17.82 in 1970 to 17.60 in 1980 but drops sharply to 14.18 percent in 1990 and increases only slightly to 15.71 percent in 2000. The crunch will not come until the late 1980's in terms of number of people from which to draw, *but it will come*. Following continued growth from a 1970 population of 699,524 to 743,434 in 1980, by 1990 the Tennessee population of ages 15-24 will decline dramatically to 646,504 and will only recover partially to 766,295

in 2000. Those in the 15-24 age category in 1990 would have been born between 1966 and 1975 and reflect the significantly lower fertility of that period. This may provide a breathing period for educational institutions in which the emphasis could shift from construction of dormitories to the initiation of new and improved programs, acquisition of much needed teaching aids, an increased emphasis upon research rather than instruction, and the improvement of classroom facilities. The effect of population trends during this period will have a decided impact upon the funding levels of programs that depend upon formula allocations. Unless program budgeting is adhered to, or unless the formulas are substantially restructured, there should be a definite reordering of the state's funding priorities during the years surrounding 1990.

Fourthly, as the reports of the 1970 Census of Population were released, concern was expressed by the business community over the drop in population under age five and its accompanying significance for markets in toys and other child products. A Knoxville paper, for example, stressed that "... the country wouldn't last very long if everybody stopped having babies at once."⁴ With the leveling and subsequent rise in fertility during the late 1960's and early 1970's, and as a result of large cohorts of women entering their peak childbearing years during the early 1970's, the percentage of the population that is under age five will increase from 8.28 to about 9.28 percent in 1980 but will again begin to decline relative to other age groups. By 1990 it will comprise 8.64 percent and 8.14

⁴"The Baby Boom Is Over," The Knoxville News-Sentinel (September 14, 1971), p. 12, col. 1.

percent in 2000. The concern over that market segment is ill-founded since population under five will increase from 324,924 persons to 396,732 during the 1970-2000 time period.

Comparison with Other State Projections

It has already been emphasized that the Tennessee population would grow by about 7.4 percent between 1970 and 1980 if its rate of change held the same relationship to the United States rate as it did during the 1960's. This is slightly below the Series B projection of 7.6 percent for the same period. Table 1.3 presents comparative projections of total Tennessee population from the United States Bureau of Economic Analysis (BEA, formerly the Office of Business Economics), the Environmental Protection Agency (EPA), and the Bureau of the Census. The EPA projections are, in fact, an earlier series adapted from BEA but have been included as an indication of the relative level if BEA figures were extended to 2000. The Bureau of the Census projections were developed by continuing the growth rates of civilian 1977 and 1978 population projections furnished the state for use in distributing Hill-Burton health facilities funds. The projections by the Bureau of the Census contained in Current Population Reports, Series P-25, Number 477 have not been considered since they are only illustrative of alternative future population levels given either no interstate migration or a continuation of the 1960-1970 migration level.

The projections developed by BEA and EPA, both in Table 1.3 and as represented in Figure 1.1, are significantly higher than those contained in CBER Series A, B, and C, and the imputed Bureau of the Census projections.

TABLE 1.3
COMPARISON OF TENNESSEE POPULATION PROJECTIONS
BY FOUR INDEPENDENT AGENCIES

Year	CBER Series			Bureau of the Census	Bureau of Economic Analysis	Environmental Protection Agency
	A	B	C			
1930				2,616,556		
1940				2,915,841		
1950				3,291,718		
1960				3,567,089		
1970				3,926,018		
1980	4,358,959	4,224,325	4,153,984	4,315,000	4,553,000	4,456,200
1990	4,830,610	4,556,139	4,378,467	--	5,288,000	5,196,000
2000	5,331,712	4,875,268	4,555,715	--	--	5,950,400
2010	--	--	--	--	--	6,873,000
2020	--	--	--	--	--	7,955,300

Source: Series A, B, and C - The University of Tennessee Center for Business and Economic Research; Bureau of the Census - Imputed by continuation of growth rate between 1977 and 1978 civilian projections released for allocation of Hill-Burton health facilities funding, plus military residents estimated at 25,200. Bureau of Economic Analysis - Survey of Current Business (April, 1972), p. 34; Environmental Protection Agency, Population by County, Historic (1940-1970) and Projected (1980-2020), Region IV, Atlanta, Georgia (July, 1972).

The divergence of the BEA-EPA figures is primarily a function of their reliance on earlier projections by the Bureau of the Census containing assumptions of fertility well above levels projected more recently. The imputed Bureau of the Census projections for 1980 lie between the Series A and B figures. A series of employment projections recently released by the Tennessee Department of Employment Security implies a projected 1975 Tennessee population slightly below the Series B projections. A further comparison concerning the labor force is discussed in Chapters 4 and 5.

Historical rates of decennial population change and levels projected by the various agencies are contrasted in Table 1.4. The higher populations

projected by BEA-EPA are reflected in substantially greater rates of increase than have occurred in Tennessee or are projected in the other series.

CHAPTER 2

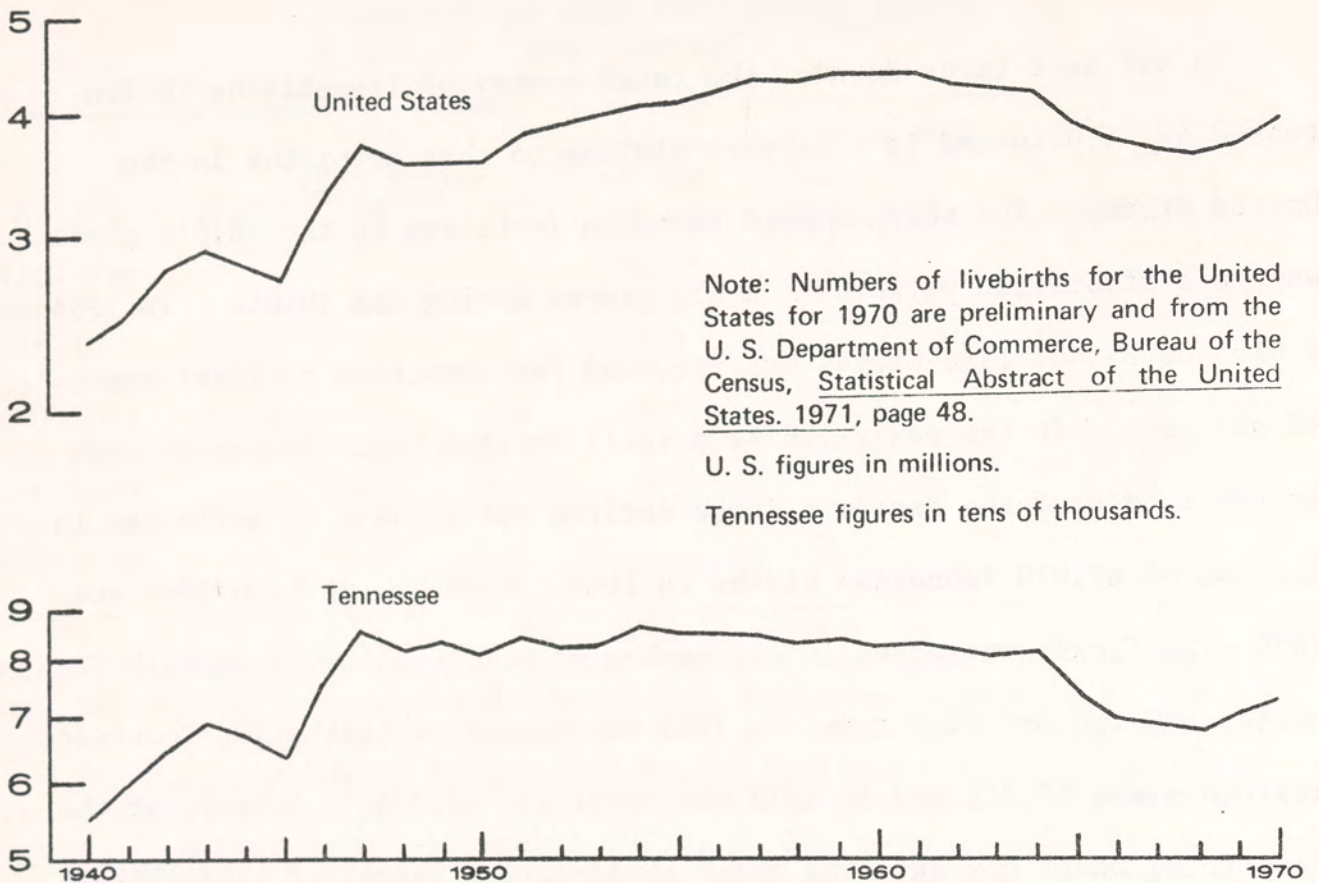

FERTILITY TRENDS AND PROJECTIONS

In the past three decades the total number of live-births in Tennessee has fluctuated in a pattern similar to that of births in the United States. The sharp upward trend in fertility in the 1940's gave way to a stabilized pattern at a high level during the 1950's. In 1954 a high of 85,401 live-births was recorded for Tennessee resident women of all ages. In the early 1960's a small decline began to emerge, and by the middle of the decade a large decline was evident as reflected in the low of 67,029 Tennessee births in 1968. However, in both 1969 and 1970 significant increases in the number of births occurred in both Tennessee and the United States; in 1969 the number of births for Tennessee residents was 69,921 and in 1970 the total was 72,723.¹ Because of the many young women now entering their childbearing years, it seems likely that this trend will continue for three to five years before leveling at 78,000-80,000 births.

Similarities between Tennessee and the United States trends in the number of births are evident in Figure 2.1. The coincidental turning points in 1946, 1948, 1950, 1964, and 1968 indicate that Tennessee is likely to continue in a pattern parallel to that of the United States. The magnitudes of change, as shown on the semi-logarithmic scale, are also generally similar.

¹Tennessee Department of Public Health, Annual Bulletin of Vital Statistics 1970, Table I.

FIGURE 2.1

Trends in Tennessee Fertility Rates

The generally declining pattern of both total and age-specific fertility rates (ASFR's) for Tennessee is demonstrated in Table 2.1 and Figure 2.2. In the older age categories the tendency begins earlier in the twenty-year period, 1950-1970, and extends further toward 1970 than the younger age categories. Note, for example, that the peak rate just preceding the general fertility declines occurred in 1950 for the 40-44 category and in 1955 for the 35-39 and 30-34 age groups. The comparable high did not occur until four years later in the 25-29 and 20-24 age groups.

1968	2.3	81.5	86.4	158.8	114.3	59.4	27.7	9.1
1969	2.3	84.0	86.5	162.5	121.0	60.3	28.5	8.2
1970	2.4	86.0	90.4	165.3	124.4	60.8	26.5	7.2

Notes: Total fertility rate (TFR) equals the summation of age-specific fertility rates (ASFR) multiplied by five.

General fertility rate (GFR) is the birth rate per 1000 female population between the ages of 15 and 44.

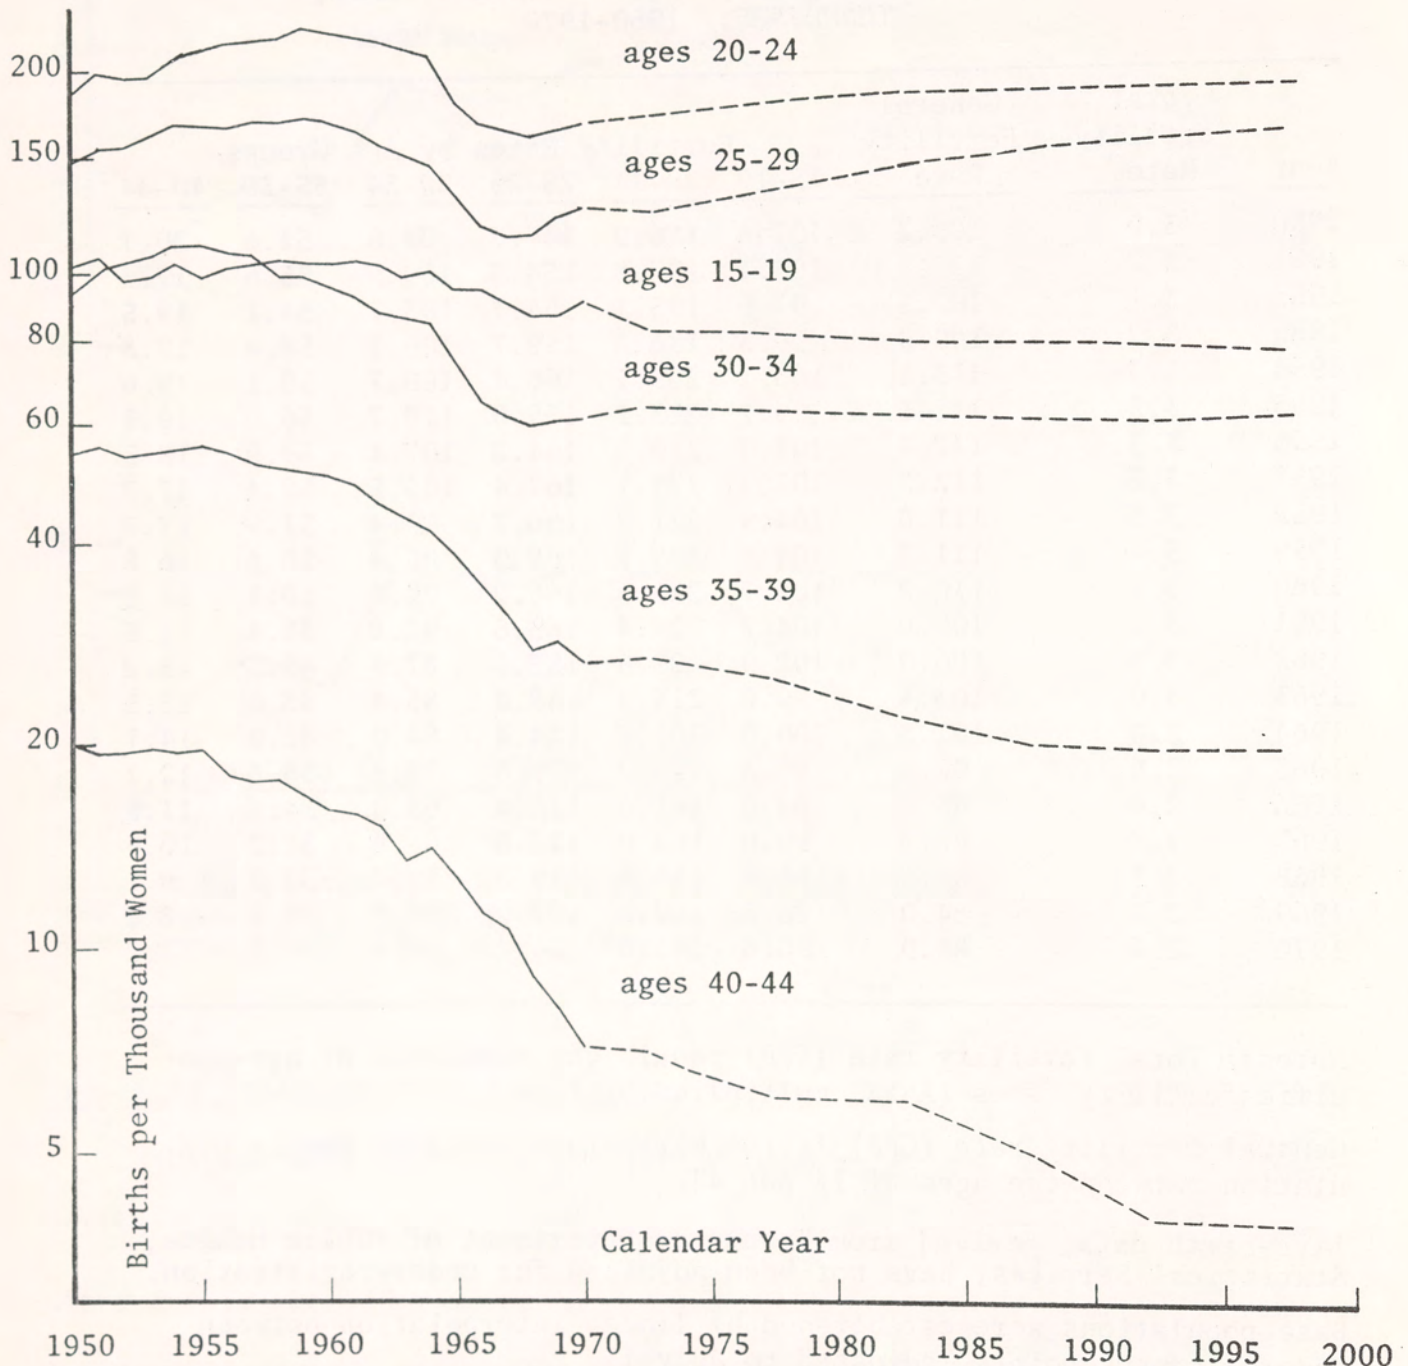

Live-birth data, derived from Tennessee Department of Public Health, Statistical Services, have not been adjusted for under-registration.

Base populations were established by linear interpolation between federal census points, adjusted to July 1.

Births to mothers of unknown age have been distributed proportionally and are included in the 15-44 age category.

Source: The University of Tennessee Center for Business and Economic Research.

FIGURE 2.2

Note: Projected rates are centered on each 5-year period, therefore the graphs do not extend to year 2000.

Source: Plotted from Table 2.1 and Series B projections, Center for Business and Economic Research, The University of Tennessee, Knoxville.

A further differential by age may be observed in the 1968-1970 period. Note the inflection at the end of the curves in Figure 2.2 for all age categories 20-24 through 30-34. Comparable increases in rates for 1969 and 1970 are not found in the two older categories, and the rise in the rate for women 30-34 is noticeably weaker than for the younger age groups. The low point in fertility rates over the twenty years occurs in 1970 for the 40-44 and 35-39 categories, 1969 for the 30-34 group, 1967 for women of ages 25-29, and in 1968 for the two youngest categories.

The dramatic change in fertility level of women in the older three categories over the course of the last 15 years implies that the substantial progress in contraceptive techniques during that period, providing convenient and reliable checks on pregnancy, has given women who desired to limit or terminate their childbearing a means for doing so.² The impressive decline in the number of large families accompanies that tendency. Most couples practice rather casual family planning (with the exception of child spacing) until their desired family size has been reached. At that point they begin to attend to contraception with more interest and care.³ Medical advances of the last two decades have made this a great deal easier and far more effective.

It is significant that the Total Fertility Rate (TFR) was affected little by the events of the 1968-1970 period. The TFR is an attempt to convert age-specific fertility (fertility at a specific point in time) to cohort terms. It is interpreted as the number of children born to a particular group of women during their childbearing careers if they conform to the fertility rates measured at some one point in time. Table 2.1 shows that Tennessee is approaching the 2.11 replacement level so widely acclaimed by Zero Population Growth advocates. However, since reaching the 2.4 level in 1965, (1) there has been only minimal further downward movement, and (2) the readjustments that have taken place in some age-specific rates have had little cumulative impact upon the TFR.

Fertility Projections

The assessment of trends in the fertility component of projections of population change is difficult because of the unpredictability of the influence of external forces. A multiplicity of causal factors interact to make the problem of prediction complex. Furthermore, variations in fertility for counties and other areas with small populations often are exaggerated.

Projection of fertility rates for Tennessee progressed in three stages. First, ratios of Tennessee to United States average annual age-specific fertility rates were derived for three time periods. These were census-centered on 1950 (1949-1951), 1960 (1959-1961) and 1970; a three-year period could not be used for 1970 due to nonavailability of 1971 birth records. In addition, it was necessary to estimate 1970 age-specific fertility rates for the United States. The change between 1966

and 1968 in the general fertility rate for the United States was calculated from National Center for Health Statistics data. Likewise, change calculations were made for the total and United States age-specific rates, and these changes were related to the change in the general fertility rate.⁴ Using the United States general fertility rate for 1970 and applying the change ratios between 1966 and 1968 in the age-specific rates, basic 1970 age-specific fertility rates for the United States were obtained.

Calculation of Tennessee-to-United States ratios of age-specific fertility rates for the three periods enabled an assessment of the convergence, divergence, or stability of the rates between the two areas. Assumptions based on these changes were constructed for the projection period. The age-specific fertility rate ratios were then projected for the state for each of the five-year projection periods according to the explicit age-specific fertility assumptions.

As the second stage in projecting the fertility component, the Tennessee-United States convergence assumptions used for the fertility rate ratios were applied to the terminal year of each five-year projection period and then were centered on the mid-point of that period through linear interpolation. For age category 15-19, the ratio was assumed to converge linearly with the 1959-1961 ratio (1.1672) in the year 2000. The ratio for age category 20-24 was assumed to remain at the 1970 level

⁴U.S. Department of Commerce, Bureau of the Census, Statistical Abstract of the United States, 1971, Table No. 60, p. 49.

of 1.0073. The 25-29 age group ratio was assumed to reach unity in the year 2000. For the 30-34 age category, the 1949-1951 ratio (.9267) was assumed for 1980 and was converged from there to unity in 2000. The 1970 ratio (.81040) was assumed for 1980 and 1990 for the 35-39 age group, and was assumed to converge from there to unity in 2030. The 1970 ratio (.7579) was used for the 40-44 age category for 1980, converging to the mean of the 1959-1961 and 1970 ratios (.8699) in the year 2020.

Third, from the four series of projections of central age-specific fertility rates prepared by the Bureau of the Census for the United States, a specific series was selected for each age category as the medium or "most likely."⁵ The criteria for selection of a series for a particular age-of-woman category were (1) proximity of the 1970 projected rate to the actual rates⁶ and (2) the degree to which the resulting projected trend for Tennessee corresponded with the historical pattern of rates for the age category. Series D was selected for the 15-19 and 20-24 age groups, an average of Series C and D for the 25-29 age-of-woman category, and Series E for the remaining age categories. Once the series had been established, the projected ratios of Tennessee-to-United States for corresponding age groups were applied to derive the medium projection of fertility rates.

⁵U.S. Department of Commerce, Bureau of the Census, Current Population Reports, Series P-25, No. 470, "Population Estimates and Projections," p. 52.

⁶The projections were released November, 1971 and they incorporated historical data through 1969.

The same projected ratios of Tennessee-to-United States age-specific fertility rates were applied to a higher or lower projected U.S. fertility rate to obtain a high and low projection. As an illustration, the medium projection of the age 15-19 fertility rates for Tennessee is based upon the Series D projection for the U.S. The high fertility rates for Tennessee are derived from the Series C and the low from Series E of the U.S. projections.

Final high, medium, and low projections of age-specific fertility rates for Tennessee resulting from these procedures are presented in Table 2.2, (the medium series is also shown in Figure 2.2). Although the medium series is intended as a most likely course of events, the variability of the fertility component suggests that a more realistic expectation is that the actual fertility trend will fall within the broader high-to-low range. Since the Tennessee rates are based in part upon the U.S. fertility projections, they are subject to the assumptions upon which the U.S. projections are predicated. Those assumptions are based upon a cohort analysis of childbearing in the U.S. and an estimated completed cohort fertility level. In some cases those estimates are less applicable to Tennessee, even though an adjustment is made through the Tennessee-to-United States ratios. For example, there is little evidence of a continued upturn in fertility rates among the 20-24 age group in Tennessee. The Tennessee-United States ratio has helped to dampen the effects of that assumption somewhat but it is still evident. Nonetheless, the projections represent the most reasonable and well-founded series currently available and should approximate reality within tolerable limits.

Planning and Development Regions and Counties

Age-specific fertility rates for smaller areas within Tennessee were projected with the same method as for Tennessee but using state rates as the basis. No assumptions of rate convergence or divergence were constructed here. Rather, 1970 ratios of age-specific rates to corresponding rates for the state were applied with the assumption that these would remain constant throughout the projection period. Thus age-specific rates for each region and county were assumed to have their own relationship to the comparable age-specific rates for the state. This subarea-to-state ratio was used throughout the projection period. By applying the subarea age-specific rate ratios to the projected state age-specific fertility rates, the projected subarea age-specific fertility rates were obtained.

CHAPTER 3

MORTALITY TRENDS

The study of mortality trends incorporates the comparative analysis of deaths and death rates over a specified period of time. This section will present significant findings based on the analysis of mortality trends in the State of Tennessee and the United States over the three decennial periods 1940 through 1970, then will outline the assumptions and techniques utilized to project the mortality component of the population projections.

Since 1940, the total number of deaths annually in the State of Tennessee increased from 29,231 to 38,079 in 1970. In 1950, there were 29,197 deaths in the state, and in 1960, 32,625 deaths were recorded. Correspondingly, the total population of the state increased from 2,915,841 in 1940 to 3,926,018 in 1970.

With regard to crude death rates, including total, male, and female rates, Tennessee appeared to have a favorable mortality experience in relation to the United States as a whole from 1940 through 1955 (see Table 3.1). However, over the 1955-1970 period, the crude death rates in Tennessee increased substantially in contrast to the leveling of the U.S. rates. Does this indicate that death rates are on the increase in Tennessee? This question may be answered in part by examining the changing age composition of the population. In 1940, Tennessee had a large proportion of young people in its population. The median age for the state was 25.8, whereas the median for the United States was 29.0. Since 1940, the population in Tennessee has been aging, in contrast to the declining

median age experienced by the United States as a whole. In 1970, the median age in Tennessee had increased to 28.1, identical to the United States figure. Therefore, Tennessee now has a greater proportion of older persons in its population among whom the risk of death is greater. To remove this influence of age structure from the death rates, the crude rates for Tennessee have been standardized to the 1940 Tennessee age distribution and are presented in Table 3.2. Comparing these rates with those in Table 3.1, it can be seen that crude death rates in Tennessee have, in fact, declined in all cases except one over the period 1940-1970 (male crude rates increased from 1960 to 1970) when the age distribution is held constant. Hence, the increase in the unadjusted

crude death rates for Tennessee are due implicitly to the changing age composition, not necessarily to an increasing death rate.

The standardization technique used above can also lend insight to the comparison of the general level of mortality in Tennessee with that of the United States. By standardizing the death rates of Tennessee to the age distribution of the United States population, variations in the age composition noted earlier are removed. Table 3.3 indicates that for each decennial period 1940-1970, death rates for both males and females in Tennessee were above those for the United States as a whole, when applying the same age distribution. This finding is masked in the crude rates of Table 3.1, since inspection of this table implies that death rates in Tennessee are below the national average. Though death rates in Tennessee have traditionally lagged behind the United States rates, there is now a trend toward convergence of the two rates.

	Tennessee	10.1	8.7	8.2	8.2

^aState rates are adjusted to the age distribution of the United States population.

Sources: United States population: U.S. Department of Commerce, Bureau of the Census, Census of Population, Characteristics of the Population, 1940, Vol. IV, Part 1, p. 12; 1960, Vol. II, Part 1, pp. 148-149; 1970, PC(1)-B44, pp. 269-270.

Crude death rates for the United States were obtained from Table 3.1. Crude death rates for Tennessee were calculated from age-sex-specific death rates presented in Table 3.4.

A more meaningful comparison of historical trends in mortality can be made by incorporating age-specific mortality data. It has already been shown how pronounced shifts in the composition of a population over time can make the comparison of crude death rates both unrealistic and misleading. Table 3.4 presents detailed age-specific mortality rates by sex for the State of Tennessee over the three decennial periods 1940-1970.

Age-sex-specific mortality rates for Tennessee generally conformed to the downward trend typical of most areas within the United States. Between 1940 and 1960, Tennessee made rapid improvements in its mortality experience as death rates decreased in all eleven age categories for both

Tennessee population by age and sex: U.S. Department of Commerce, Bureau of the Census, Census of Population, Characteristics of the Population, 1940, Vol. II, Part 6, p. 563; 1950, Vol. II, Part 42, p. 35; 1960, Vol. I, Part 44, pp. 32-33; 1970, PC(1)-B44, pp. 49-50.

sexes. The most pronounced improvement has been made in the youngest age groups, particularly the first year of age. The rate for males in this age category decreased from 64.8 in 1940 to 25.5 in 1970, a decline of 61 percent. Comparative rates for females were 48.9 and 20.5, a decline of 58 percent.

It should be noted that decreases in mortality in the most recent periods have not been of the magnitude that occurred in the earlier periods. This is particularly the case when the 1970 age-specific rates are brought into focus. From 1960 to 1970, death rates for females in Tennessee declined in all age categories except two. However, for the same period, the comparable rates for males decreased in only three age categories and increased in seven age groups. The increase was most significant for the middle age categories (15-24 through 55-64). This rise in male mortality is not peculiar to Tennessee. Comparable age-sex-specific data for the United States show a similar, though not as pronounced, increase in mortality for the middle age categories. It appears that the recent increase in male age-specific mortality rates can be partially explained by the rising accident rates (primarily motor vehicle) that take their greatest toll on younger males, and the higher incidence of heart diseases and malignant neoplasms among American males today.

Two more findings merit attention in the analysis of age-specific mortality data for Tennessee and the United States. First, the comparison of age-sex-specific mortality data for Tennessee with comparable data for the United States (Table 3.5) reveals two historical trends: (1) for the older age categories (age groups 55-64 and above), age-sex-specific mortality rates for Tennessee have been consistently below

those of the United States, particularly for the terminal age category of 85 and over, and (2) for age categories below 55-64, Tennessee rates have been traditionally above those of the United States, particularly infant mortality rates. Moreover, the disparity between the Tennessee and United States age-sex-specific rates is diminishing over time, that is the trend is toward convergence of the two rates.

The second finding that should be mentioned is the characteristic sex differential in mortality. Mortality among females, almost without exception, has traditionally been below that for males. Comparison of Tennessee male and female death rates by age categories in Table 3.4 illustrate this point. Additionally, female mortality rates have shown greater and more consistent improvement than comparable male mortality over time. For instance, in Tennessee, female death rates declined from 1940 to 1970 by over 40 percent in eight of the eleven age categories, whereas for the male mortality experience this claim can be made for only four age categories. With the recent upswing in male death rates for the middle age categories, the sex differential in mortality is more pronounced than ever.

In summary, the following major observations regarding trends in mortality for the State of Tennessee and the United States as a whole can be made:

1. The downward trend in mortality is continuing at a substantially reduced rate, with the exception of selected male age categories in which mortality rates increased from 1960 to 1970.
2. Death rates for Tennessee remain above those for the United States in the younger age categories, but indicate a tendency toward convergence.

3. Death rates for Tennessee remain below those for the United States in the older age categories, but indicate a trend toward convergence.
4. Mortality conditions for younger age categories have improved more rapidly than those for older ages.
5. Mortality among females has traditionally been below that for males and has shown a greater average decline.

ASSUMPTIONS AND PROJECTION OF MORTALITY

With past and current mortality trends as a foundation, attention can now be directed toward projecting the mortality component of the population projections for the State of Tennessee.

Life Tables

A principle step in the projection of the mortality component was the construction of abridged life tables for the United States, the State of Tennessee, and each planning and development region in Tennessee for 1949-1951, 1959-1961, and 1970. These life tables were used to compute age-sex-specific survival rates for the United States, the state, and each region. Life tables for 1959-61 and 1970 for the State of Tennessee and for each of the nine planning regions are found in Appendix I. A three-year period could not be used for 1970 because data for 1971 is unavailable.

The life table is a hypothetical life history indicating what would happen to a synthetic cohort of people experiencing no migration and who were subjected to a fixed schedule of age-sex-specific mortality rates. The life tables in Appendix I are abridged in that they have been constructed for five-year age groups rather than single years of age.

The four columns having most meaning to data users are those labeled nqx , nLx , ex , and $SRATE$. The nqx column is the life table equivalent of age-sex-specific mortality rates. These form the basis for the development of all other columns in the life table. The nLx column indicates, within the life table conceptual framework, what the age distribution of the stable life table population would be were a census of the life table population conducted.

The ex column is of most popular interest. These figures indicate the average number of additional years a person living in a corresponding age category can expect to live. Table 3.6 presents the 1959-1961 and 1970 estimated average length of life by sex for the United States, the State of Tennessee, and each region as derived from the life table. For illustration, the average Tennessee male at age 0-1 in 1959-1961 can expect to live 66.7 more years, and the average female of age 0-1 may expect to live 73.1 more years. Analysis of Table 3.6 reveals four significant facts:

1. Life expectancy at birth in the State of Tennessee is slightly below that of the United States as a whole.
2. At birth, females in Tennessee can expect to live at least six years longer than males.
3. Male life expectancy has declined over the 1960-1970 period.
4. The four metropolitan regions (Regions 2, 3, 5, and 9) have, in almost all cases, lower male and female life expectancies than do non-metropolitan regions.

The last column of the life tables, the column labeled $SRATE$, provides the basic figure for projection of the mortality component. The $SRATE$ (survival rate) may be interpreted as follows: in the male

TABLE 3.6

Luman H. Long, ed. The World Almanac, 1972, Newspaper Enterprise Association, Inc., p. 89.

Tennessee: Life expectancies are obtained from life tables in Appendix I.

life table for Tennessee, on the average .973830 of the males born will live to be 0-1 years of age. Similarly, .991820 of the males age 15-19 will live to be 20-24 on the average. Survival rates in three age categories deserve special mention. The first rate shown in the *SRATE* column represents average survival from birth to the age category 0-1. The second rate indicates average survival from birth to ages 0-4, and the

last rate represents survival from the age category 80 and over to the category 85 and over. All other rates indicate survival from the previous age category.

To construct life tables by region, deaths by age and sex were aggregated for all counties within a region to produce death totals for each region. Death rate values (nm_x) by region were computed by applying population figures aggregated from counties to the region death totals. To convert nm_x to nq_x values, the Reed-Merrell Method was employed. Once the nq_x values were determined, construction of the remaining columns of the life table were straight forward.

Two cautions must be observed in interpreting the contents of the tables. First, some differences will be observed between the Tennessee table and the table released earlier by the National Center for Health Statistics. These are due to small variations in the formulae used to derive figures for the various columns of the tables. Treatment of the separation factors and formulae for the first and last age categories results in the largest differentials. However, any differences that are observed in early columns of the table tend to produce trivial differences in the life expectation and survival rate columns.

Finally, census-centered data have been utilized in an attempt to improve the reliability of the death rates and subsequent life tables. Nonetheless small numbers of deaths occurred occasionally in age-sex categories for the smaller regions. Annual fluctuations will be somewhat more pronounced, of course, in tables developed from 1970 mortality only.

State Projections

As mentioned previously, the general long-term trend of mortality rates in Tennessee is a convergence toward the United States rates. The projection of age-sex-specific survival rates for Tennessee incorporates the assumption that state survival rates for all age-sex-categories will converge linearly with those of the United States. To determine the rate of convergence, a ratio of the Tennessee survival rate to the United States survival rate was computed for each age and sex category for each period 1949-1951, 1959-1961, and 1970. Plotting these ratios in chronological order, a line of best fit could be drawn through the three points to measure the rate of convergence for a given age and sex category. Linear interpolations were made between the ratio at convergence (1.0) for each age and sex group and the corresponding ratio in 1970 to obtain the Tennessee-to-United States survival rate ratios for the intervening five-year time segments. Convergence for most age and sex categories occurred before the year 2000.

The basic source for projection of the Tennessee survival rates is the schedule of projected five-year age-sex-specific survival rates for the United States for the periods 1970-1975 through 1995-2000, published by the Bureau of the Census.¹ Projected five-year survival rates for the State of Tennessee were produced by applying the Tennessee-to-United States survival rate ratio for each age-sex-group to the corresponding

¹U.S. Department of Commerce, Bureau of the Census, Current Population Reports, Population Estimates and Projections, Series P-25, No. 470, p. 54.

projected United States survival rate for each five-year projection period. The resulting projections of mortality for the State of Tennessee are shown in Table 3.7.

County and Regional Projections

It should be recalled that population projections for Tennessee as a whole and for regions and counties were derived separately. This included a separate set of survival rates for counties and regions apart from those of the state.

The derivation of projected survival rates for regions was based upon survival rates projected for the state. Ratios were computed between 1970 age-sex-specific survival rates for each region and the corresponding 1970 age-sex-specific rate for the State of Tennessee. These calculations were repeated for 1959-1961 survival rates. A mean ratio was obtained by weighting the 1970 ratio by 0.7 and the 1959-1961 ratio by 0.3. This resulting region-to-state relationship was assumed to remain constant throughout the projection period. Projected survival rates for regions were subsequently obtained through application of the mean ratios to age-sex-specific five-year survival rates projected for the state for each five-year time segment through the projection period. It was assumed that survival rates for regions would also apply to all counties within each region. This assumption was made necessary by unreliable and fluctuating rates for individual counties where populations are frequently small and number of cases in age-sex-specific categories are even smaller.

CHAPTER 4

THE MIGRATION COMPONENT

Population movement between regions and states is a major component of population change. Outmigration from Tennessee to other states has been prevalent since 1940, as shown in Table 4.1. In the decade of 1950-1960, a high level of outmigration contributed to the relatively small percentage growth in Tennessee population, 8.4 percent, as compared with United States population growth of 18.5 percent.

In the 1940-1950 and 1960-1970 decades, outmigration was a smaller factor; this was reflected in a closer positive relationship in percentage change between population growth in Tennessee and the United States. Tennessee's growth rate between 1940 and 1950 was 12.9 percent, while that of the United States was 14.5 percent; between 1960 and 1970, Tennessee's increase was 10.1 percent while the United States increased by 13.3 percent.¹ During these decades there was an outmigration from Tennessee of 55,000 between 1940 and 1950 and 45,000 between 1960 and 1970.

Age-specific comparisons in migration patterns, presented in detail in Table 4.2, show some variations between the 1950-1960 decade and the 1960-1970 decade. In 1960-1970 a much larger proportion of outmigration was accounted for by the 0-9 age cohort. This suggests significant outmigration in the young adult category, which fact is evident in the sizable

¹Tennessee 1960-1970 percentage change of 10.1 is based upon the revised State 1970 total population of 3,926,018 released by the Bureau of the Census.

outmigration figures presented for the 20-29 age group. In other age categories between 1960 and 1970, migration was a relatively small factor. In contrast, during the 1950-1960 decade, outmigration was significant in all age categories between 5 and 50. From this it appears that some change in migration patterns has occurred, although there remains a high level of outmigration in the young adult group. Determination and pursuit of career opportunities are evidently major factors in departure from Tennessee. It is significant that in recent years a much larger proportion of men than women have left the state, both in the young adult years of 20-29 and in total numbers. During the 1950's approximately 52 percent of the total net outmigration was contributed by males. Between 1960 and 1970, however, 70 percent of the migration was due to movement of the male population across state boundaries. Particular importance is attached to the fact that although total male net outmigration was approximately 110,000 higher

Source: Gladys K. Bowles and James D. Tarver, Net Migration of the Population, 1950-60, by Age, Sex and Color, Volume I, Part 4, Tennessee, Table 1 (U.S. Government Printing Office, 1965); and Richard A. Engels, Tennessee Population and Housing 1950-1970, Part II: Age, Sex and Migration. Center for Business and Economic Research, The University of Tennessee and Tennessee State Planning Commission, 1972.

during the 1950-1960 decade; outmigration of males in the 20-24 year age category was about 6,000 higher during the 1960's.

The tendency for the state to continue to lose young adults through outmigration and simultaneously to have the population become progressively more urban (52.3 percent in 1960 and 58.8 percent in 1970) is reflected in a comparison of migration patterns for rural and urban areas.² The 28 counties that were 100 percent rural in 1970 experienced an average total net outmigration rate of 6.9 percent for the 1960 decade while the 18 counties that were at least 50 percent urban in 1970 registered an average net immigration of 1.5 percent during the same period. Of course, those leaving rural areas are not necessarily lost to the state. There is a strong indication, however, that they are seeking training and careers that take them to urban areas of both Tennessee and other states.

An alteration in the pattern of migration for the older age categories carries with it particular implications for public and private institutions providing services for the aging. During the 1950-1960 decade, net migration of those in the 60-and-over age category at the end of the decade had added only 2,000 persons to the population. Migration for the same age group during the 1960's added 29,000 persons. Such changes carry with them rather fundamental requirements on the resources of the state. Although the emergence of Tennessee as a retirement haven is clearly not indicated in these data, the continued outmigration of

²Richard A. Engels, Tennessee Population and Housing, 1950-1970, Part II, Age, Sex and Migration, Center for Business and Economic Research, February, 1972, p. 34, et passim.

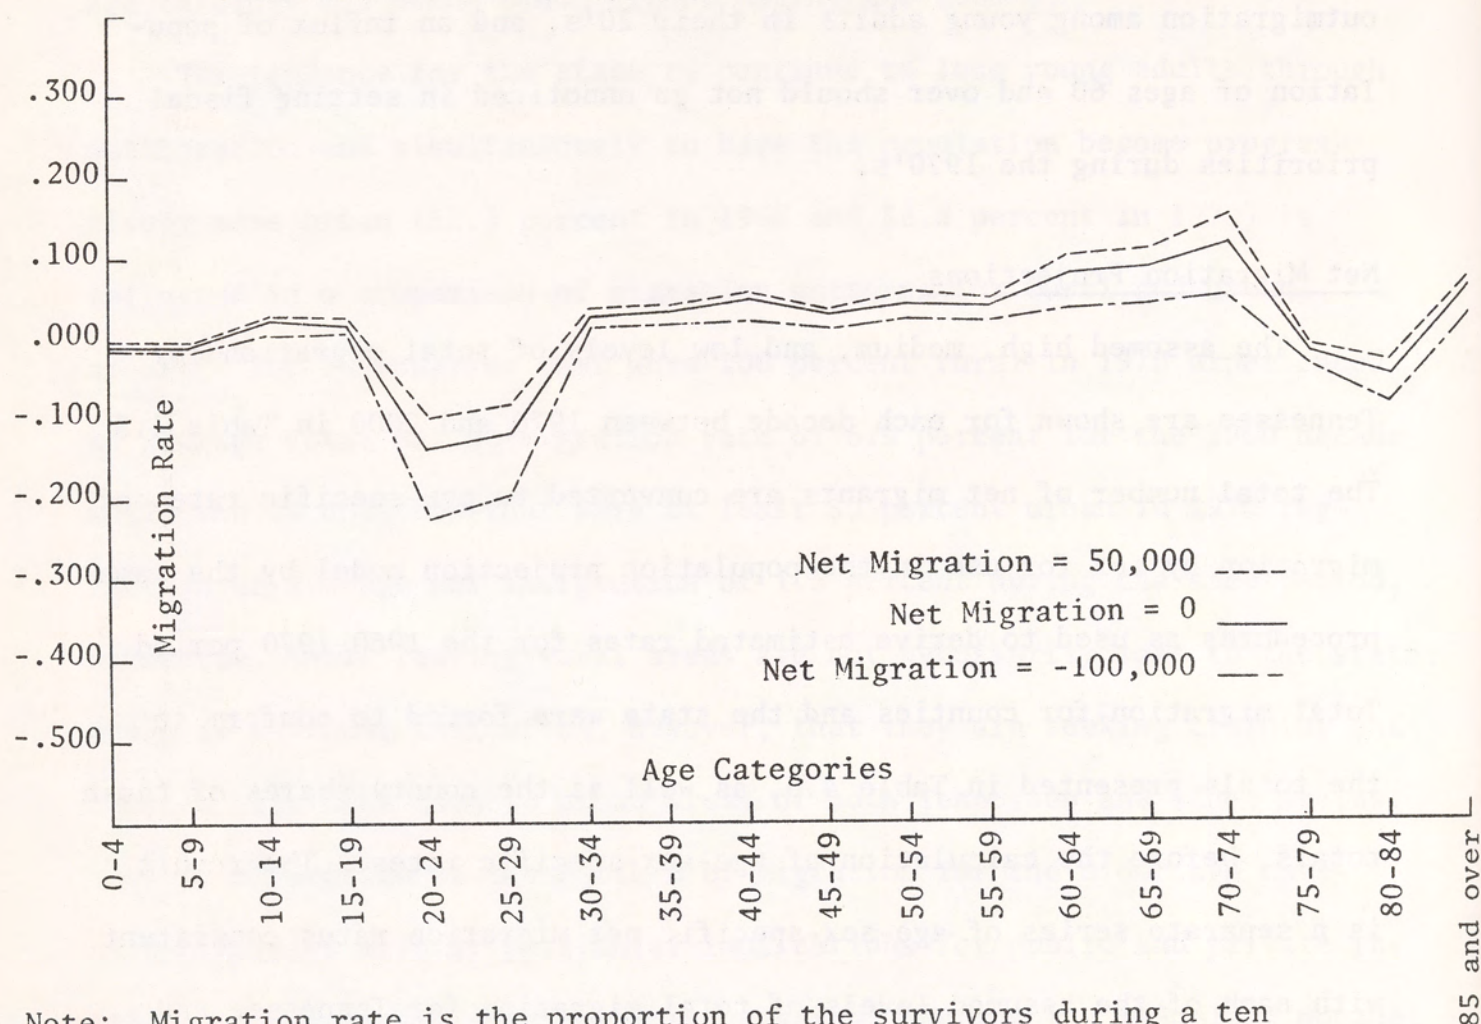

population in ages 0-9, coupled with recent low fertility levels, heavy outmigration among young adults in their 20's, and an influx of population of ages 60 and over should not go unnoticed in setting fiscal priorities during the 1970's.

Net Migration Projections

The assumed high, medium, and low levels of total migration for Tennessee are shown for each decade between 1970 and 2000 in Table 4.3. The total number of net migrants are converted to age-specific rates of migration by sex for use in the population projection model by the same procedures as used to derive estimated rates for the 1960-1970 period.³ Total migration for counties and the state were forced to conform to the totals presented in Table 4.3, as well as the county shares of those totals, before the calculation of age-sex-specific rates. The result is a separate series of age-sex-specific net migration rates consistent with each of the assumed levels of total migration for Tennessee and the counties. The trend of migration by age is one of the most reliable relationships found in the demographic literature. Regardless of the level of total migration, or whether the total is positive or negative, the profile described by the curve of migration by age is strikingly similar. Figure 4.1 shows age-specific migration rates for males that have been controlled to the three hypothetical levels of 50,000, zero, and -100,000 net migration for Tennessee. Although there is variation in the location of the curves vertically on the chart, the configurations

are identical. The same tendency is found for different time periods and is observed at the state and county levels.⁴ The strength of this pattern is a strong argument for the type of adjustment procedure used.

⁴Ibid., p. 3.

It also is a consideration in the selection of the total migration levels for the medium assumption. Notice the heavy 1950-1960 outmigration among the 20-34 age groups and again during the 1960's for ages 20-29. Also in Figure 4.1 the net migration rates for males in the 20-24 and 25-29 age groups remain strongly negative even when the total migration level is set at 50,000 immigration. Continued outmigration for the 20-29 age group in coming decades is nearly a certainty. Furthermore, large numbers of young people will be making early career decisions, and as a result the 15-19 age category is likely again to become an outmigration group. And unless rather substantial economic development programs are initiated early in the 1970's, the outmigration pattern may again extend into the 30-39 age group as attractive high-growth industries in other states experience more favorable economic conditions during the decade. The magnitude of the effect upon the population is illustrated in a simple cohort analysis. The Tennessee population in the 15-34 age

category alone (historically the high outmigration group) was greater by 215,500 in 1970 than in 1960. If the change in the entire age structure between 1960 and 1970 is considered, some interesting parallels may be drawn between migration in the 1960's and what may be anticipated in the 1970's. The change in age distribution and relative size of age cohorts from 1960 to 1970 will contribute approximately 5,000 more outmigration during the 1970's than occurred during the 1960-1970 decade. This conclusion assumes that the migration rates of the 1960's will hold for another decade. If the migration rates of the 1950's are used, however, the comparable figure would be approximately 36,000 more outmigration during the 1970's than during the 1960's as a result of changes in the age structure. Were the actual increase to be an average of the two, 20,500 more outmigration could be expected during the 1970's. The result would be a total net migration during the 1970-1980 decade possibly ranging from -81,000 to -50,000 or at an average -65,500. Such considerations have led to the expectation of increased outmigration at the -75,000 level for the 1970-1980 decade, decreasing gradually to -45,000 for 1980-1990 and zero net migration for 1990-2000.⁵

⁵In the zero net migration assumption, neither the age-sex-specific migration rates nor the control totals for counties are set at zero. If an area such as the state has an assumed zero migration, rather than age-sex category has a non-zero migration rate but the application of that schedule of rates would yield a total migration of approximately zero. To attribute a zero rate to all ages would grossly misrepresent the differentials by age.

The establishment of county total migration shares corresponding to each of the state control totals was accomplished in three stages: (1) counties with unusually high positive or negative migration during the 1960-1970 period were identified and adjusted, (2) the total net migration for all counties was readjusted by a plus-minus technique to the original -45,139 control total for the state, and (3) the resulting number of net migrants for each county were in turn adjusted to each assumed level of migration for the state for example, -75,000 for 1970-1980.⁶ Counties in which the 1960-1970 level of migration was revised in step 2 were Carroll, Jackson, Johnson, Meigs, Obion, Putnam, Rutherford, Sullivan, Sumner, and Weakley. These counties were selected on the basis of (1) their total population size, (2) the

⁶The adjustment factor for positive migration counties is:

$$P = 1 + \frac{t - T}{\sum_{i=1}^n M_i}$$

and the adjustment factor for negative migration counties is:

$$N = 1 - \frac{t - T}{\sum_{i=1}^n M_i}$$

where: n = the number of counties,
 i = the i th county,
 t = the new control total,
 T = the old total net migration,
 M_i = net migration for county i .

absolute relationship of net migration level to total county population, (3) whether or not their total net migration switched sign from its 1950-1960 level to the 1960-1970 period for example, -3,000 for the 1950's to +10,000 for the 1960's, and (4) the proximity of a county to a metropolitan area. Migration levels for the ten counties were revised to the algebraic average of 1950-1960 and 1960-1970. The same procedures have been utilized in the projection of regional net migration.

Projections of the migration component remain provisional for two reasons. First, since the projected levels for coming decades rely upon patterns of the 1960-1970 period, they are in part subject to the qualifications attached to the data for the base period. These include the use of 1970 Census counts that have subsequently been revised by the Bureau of the Census and the adjustment of migration totals to provisional estimates of total net migration provided by the Census Bureau.⁷ Secondly, as noted in the introductory chapter, a revised series of population projections for regions and the state will be developed and released at a later date incorporating a feedback mechanism in the migration component. That is, although initially the same migration assumptions will be used as are presented here, the projected populations will be evaluated against independently developed projections of employment as translated through age-sex-specific labor force participation rates. If the two employment levels do not match, the population will be revised through the migration component within previously established

⁷ Ibid., pp. 5-8; and U.S. Department of Commerce, Bureau of the Census, Current Population Reports, Population Estimates and Projections, Series P-25, No. 461.

tolerance limits. In this manner, any major differences between the population projections and independent employment projections may be reconciled.

The resulting levels of migration may vary slightly from those assumed here. However, Chapter 5 reviews the degree of correspondence between a recent series of employment projections by the Tennessee Department of Employment Security and the employment projections (converted to the Employment Security definitions) resulting from the population projections reviewed in Chapter 1 which were produced without the feature of migration feedback. Although variations are found for some regions, the total employment levels established for Tennessee by the two methods are virtually identical. This may be taken as an indication that the projected population developed with the migration feedback provision will show little revision from those presented in Chapter 1 and Appendix C.

Tests of Component Sensitivity

At the national level, the fundamental variable responsible for changes in the size and age structure of the population is the fertility component. In a recent article, the Bureau of the Census emphasized migration rather than fertility in accounting for population growth in the ten most populous states.⁸ However, their illustrative projections do not bear out this conclusion under close evaluation. Migration

⁸Bureau of the Census, U.S. Department of Commerce, "Interstate Migration Big Factor in Business Future Plans," Commerce Today, Vol. II, No. 14 (17 April, 1972), p. 25.

accounts for the greatest population differential by the year 1990 in only three states. In four states the greatest differential results from the fertility component and in the three remaining states there is no difference in the importance of the two components.

The results of a similar analysis for Tennessee are shown in Table 4.4. For testing purposes, migration levels were doubled from the 1960-1970 decade and used in population projections to the year 2000 while fertility and mortality were held constant. The effects of continued 1960 fertility rates were compared to population resulting from the 1970 fertility schedule while other factors were controlled. Likewise mortality rates were doubled from their 1960 level as a test of impact. The standard against which the three test runs were compared utilized Tennessee 1970 fertility rates, the 1959-1961 mortality experience, and the 1960-1970 net migration levels producing -45,000 migrants. It may be noted in Table 4.4 that the impact of changing the fertility component was approximately twice that of mortality, which in turn produced about three times the impact of changing the migration component.

Of course there is some question as to the likelihood of such rapid change in the components. The probability is low that mortality will double. As a result, it should not be given serious consideration, despite its being a relatively sensitive component. Significant changes are not infrequent for the fertility and migration components. Since fertility carries with it a multiplier effect and migration is only additive, it is doubtful that the impact of migration at the state level could ever match the importance of fertility in either a brief or extended

TABLE 4.4
DIFFERENCES OF TEST RUN TENNESSEE POPULATION PROJECTIONS IN 2000
RESULTING FROM DOUBLING OF COMPONENT RATES

<u>Component for Which Rates Were Doubled</u>	<u>Difference in Population</u>
Fertility	1,048,600
Mortality	533,700
Migration	188,300

time frame. As an illustration, net migration in Tennessee totaled -273,000 during the 1950's and -45,000 during the 1960 decade. The differential is 228,000 persons. In comparison, there would be 278,000 more population in 1980 if the 1960 birth rates were to persist through this decade than if the 1970 rates were used. Since shifts of this magnitude in fertility occur more frequently than such radical variations in migration level, even more importance is attributed to the fertility variable. The relative contributions of the components to total population change in Tennessee are unmistakable.

A hint as to the weight of the fertility component is reflected at the county level as well as in the Sumner County projections. Recall that the effect of migration was reduced significantly by averaging the 1950-1960 and 1960-1970 migration for this county. Even after the dampening of the migration influence, Sumner County is projected to increase its population by 30.4 percent by 1980. This is one of the highest percentage increases in the state for that period. Yet net migration accounted

for only 9,575 of the total 17,084 population change. This is a by-product of (1) the importance of the multiplier effect of fertility and (2) the fact that migration patterns of prior decades have implications for natural change during later years. That is, when population movement takes place, the destination will gain population not only as a result of the added migrants themselves but also from their later offspring and their subsequent children through the multiplier effect.

CHAPTER 5

TRENDS IN THE TENNESSEE LABOR FORCE

Trends and projections of the labor force are linked closely to changes in the size of the population. The main intent of this monograph has been to present population projections for the State of Tennessee and its Planning and Development Regions; however, as a consequence of the close relationship between population and labor force size, labor force projections for the State of Tennessee and its regions have been included. This section will review recent trends in the labor force and discuss the assumptions and methodology underlying the labor force projections.

Labor Force Trends

In 1960, 879,604 males and 424,379 females of age 16 and over were employed in the Tennessee labor force. In 1970, the comparable figures were 956,144 males and 595,103 females, representing 8.7 and 40.3 percent growth in labor force size.¹ The total labor force participation rate in 1970 was 71.4 percent for males and 40.0 percent for females;

¹Labor force totals are from Bureau of the Census, 1970 Census of Population, General, Social and Economic Characteristics, Tennessee, PC(1)-B44, p. 171. For sake of consistency, all labor force rates and totals in this chapter conform to the revised labor force definition, i.e., ages 14 and 15 have been subtracted from labor force totals in years prior to 1970 in all computations.

the combined total participation rate was 56.5.² The Tennessee labor force experience for the 1960-1970 period is summarized in Table 5.1. This table presents labor force participation rates by age and sex for the State of Tennessee and regions in 1960 and 1970, and the percentage change in the rates over the 1960-1970 period.

Several significant features appear when labor force trends over the past years for Tennessee and the United States are reviewed. The principle feature has been the notable change in participation in the labor force by sex. The labor force participation rates for men have been slowly declining since 1900. During this same period, the labor force participation rates for females have been steadily increasing as more and more women are seeking employment outside the home.³ This trend in Tennessee is clearly illustrated in Figure 5.1. Note that the Tennessee labor force participation rates have been consistently below those of the United States as a whole. When age-specific data are considered (Table 5.1), it can be seen that the decline in the male labor force participation rates has been due primarily to a decline in the participation rates for the youngest and oldest age groups. For the

²The labor force participation rate for a given population is computed as: $\frac{\text{total in labor force}}{\text{total in population}}$.

In order to conform with the age categories used in the population projections, a population base of ages 15 and over was used in computing all total labor force participation rates.

*CHANGE IS EXPRESSED AS A PROPORTION RATHER THAN AS A PERCENTAGE.

FIGURE 5.1
TOTAL LABOR FORCE PARTICIPATION RATES,^a
UNITED STATES AND STATE OF TENNESSEE: 1940-1980

^a Rates are based on total labor force by sex for age 16 and over and population by sex for age 15 and over. Participation Rate = $\frac{\text{number employed}}{\text{total labor force}}$

Sources: Tennessee data based on U.S. Department of Commerce, Bureau of the Census, Census of Population, Characteristics of the Population, (1940) Vol. II, part 6, p. 580; (1950) Vol. II, part 42, p. 196.

U.S. Department of Commerce, Bureau of the Census, 1970 Census of Population, General Social and Economic Characteristics, Vol. PC(1)-C44, p. 171.

U.S. Data based on U.S. Department of Commerce, Bureau of the Census, Census of Population, Characteristics of the Population, (1940) Vol. IV, part 1, p. 90; (1950) Vol. II, part 1, p. 247; (1960) Vol. II, part 1, p. 487; (1970) Vol. PC(1)-B1, pp. 269-70.

Tennessee experience over the 1960-1970 period, participation rates for the 16-24 male age category declined by 6.4 percent and the 65 and over group declined by over 17 percent. The modest rate changes for the ages 25 through 64 reflect the continued stability of this group in the labor force; that is, in these ages nearly all males are a part of the labor force.⁴ Although detailed analysis is beyond the scope of this section, the decline in the male labor force participation rates for the two extreme groups can be attributed to several factors, including fluctuations in job availability, continuing education of the younger age group which delays their entrance into the labor force, and rising family income and attractive pension plans affording earlier retirement for the older age group.

For women, there has been a significant increase in labor force participation in all age groups. Over the 1960-1970 period in Tennessee, increases in the female labor force participation rates ranged from 11.4 percent for the oldest age category to a substantial 28.5 percent increase in the 25-34 age category. Factors promoting the entrance of women into the labor force include, (1) changing job composition, in which a vast number of service and clerical jobs have been created and are employing women, and (2) long-term declines in the birth rate, permitting more women to actively seek employment.⁵ Note that the 19.7

⁴Richard A. Easterlin, Population, Labor Force, and Long Swings in Economic Growth, National Bureau of Economic Research, No. 86 (Columbia University Press, New York, 1968), p. 169.

⁵Bancroft, p. 29.

percent increase in the total female labor force participation from 1960 to 1970 in Tennessee (see Table 5.1) was accompanied by a 23 percent decline in the general fertility rate during the comparable period.⁶

Another feature in labor force trends concerns the rate of change in labor force participation rates. Male and female participation rates are not only changing in different directions, they are also changing at different rates. On the basis of past trends, there has generally been a higher level of rate changes for females than for males.⁷ This rate change disparity by sex is revealed in Table 5.1. For instance, over the State of Tennessee as a whole, the total labor force participation rate for males showed a negative change of 5.1 percent from 1960 to 1970, whereas, the comparable rate for females changed in a positive direction by 19.7 percent, almost four times greater than the male rate change.

Regional Trends

Trends in the labor force for each of the Planning and Development Regions in Tennessee significantly parallel those of the state as a whole. Over the 1960-1970 period, labor force participation rates for males declined in every region. This is reflected by pronounced declines in the two extreme age categories and moderate declines in the more stable

⁶General fertility rate is derived from Donald W. Hastings and Richard A. Engels, "Fertility Decline in Tennessee 1960-1970," Tennessee Survey of Business, Vol. 7, No. 11 (July, 1972), Table 1, p. 5.

⁷Easterlin, p. 170.

middle age groups. Similarly, participation rates for females increased substantially over all age groups in each region, the one exception being Region 1, where the 65 and over female age group registered a 1.2 percent decline. Other discernible patterns in labor force participation rates from region to region can be illuminated by comparing the participation rates for regions in Table 5.1. One pattern that is revealed is the higher metropolitan labor force participation rates, particularly female rates. For example, the Memphis-Delta Region (9), which is the most densely populated region in the state, showed male and female labor force participation rates of 79.4 and 37.2, respectively, in 1960. These participation rates were the highest in the state. At the other extreme, the least populated region, the Upper Cumberland Region (4), had comparable rates of 69.0 and 31.4, among the lowest participation rates in the state. The main exception to this urban influence on labor force participation rates was the East Tennessee Region (2), which had relatively low participation rates in both 1960 and 1970.

A second regional pattern is depicted by the change in participation rates from 1960 to 1970. Over this period, the largest rate changes for females occurred in the non-metropolitan regions, rather than in the metropolitan regions. Regarding females, the non-metropolitan regions registered, without exception, greater percentage increases in labor force participation rates over the 1960-1970 period than did the metropolitan regions. For males, this pattern was not as pronounced. The percentage decline in participation rates for males over the 1960-1970

period was greater than the corresponding state change in three of five non-metropolitan regions. This pattern of rapid change in labor force participation rates for both sexes in the non-metropolitan region can be partially explained by the growth of light industries in these areas, for example, textiles and services, that favor female rather than male employment. Further, most of the counties in these regions are rural in nature and during that period had characteristically higher birth rates than urban counties. With the substantial decrease in the birth rate from 1960 to 1970, a large proportion of women in the non-metropolitan regions were freed from child care duties to compete with men for jobs in the labor force.

Labor Force Projection Assumptions

The labor force projections in this monograph are the product of two independent sets of projections: (1) projections of population by age and sex, and (2) projections of labor force participation rates by age and sex. Projected total labor force figures were derived by applying projected labor force participation rates by age and sex to the corresponding future population of that age group and sex. Labor force projections for 1975 and 1980 by age and sex categories for the State of Tennessee and each region are presented in Table 5.2. It should be cautioned that these labor force projections are preliminary; more complete and improved projections of Tennessee labor force are in progress now and will be published in the near future.

The assumptions and methodology underlying the population projections have already been covered in detail in earlier chapters. It

 POPULATION, GENERAL, SOCIAL AND ECONOMIC CHARACTERISTICS, TENNESSEE,
 PC(1)-C94.

should be noted that labor force projections are greatly dependent on the future size and age structure of the projected population,⁸ thus the accuracy of the labor force projections will be a function of the accuracy of the population projections.

Although three sets of population projections are presented - Series A, B, and C - the labor force projections presented in Table 5.2 have been based only on the Series B set of population projections.

Projections of the labor force participation rates for the State of Tennessee and each region are based on the 1970 participation rate and the percentage change from 1960 to 1970 observed for each age and sex category. These figures are found in Table 5.1. Since both the recent and long-term trend in labor force participation rates has been one of decrease for males and increase for females, the assumption was made that this trend would continue at a decreasing rate through 1975.

To project the 1970 labor force participation rates to 1975, it was assumed that the rates would continue to change in the same direction they did during the 1960-1970 period and that they would change from 1970 to 1975 by one-fourth of the percentage change observed from 1960 to 1970 for each age and sex category.

To project the labor force in 1980, it was assumed that the participation rates observed in 1975 would remain constant through 1980; hence, the participation rates used to derive 1975 labor force projections were also applied in the 1980 projections.

⁸Easterlin, p. 157.

Comparison with Tennessee Employment Security Projections

The Tennessee Department of Employment Security (TDES) has prepared projections of work force or employment for 1975 for Tennessee and by region. No labor force projections by age or sex are made by the TDES. The assumptions and methodologies utilized by the two sets of projections, however, have distinct differences. The labor force projections of this monograph are closely related to projections of population via labor force participation rates. Hence, the assumptions made concerning fertility, mortality, and migration for the population projections also have a bearing on the labor force projections. On the other hand, the employment projections of the Tennessee Department of Employment Security do not depend on population projections. The basic component of their employment projections are individual industries and growth trends within each industry. In the Employment Security projection approach, the labor force in each industry is projected into the future based on the characteristic trends for each industry.

Since the two labor force projections discussed are prepared through two widely differing approaches, a comparison of the resulting projections is instructive. This is presented in Table 5.3 for total employment. Note the remarkably close agreement in the projected state employment total; the difference between the two figures is only 0.2 percent. The projections by region do not compare as favorably as do the state totals; however, considering the dissimilar projection methods employed, the projections for only two regions (3 and 4) appeared to be significantly different.

TABLE 5.3
COMPARISON OF 1975 TENNESSEE LABOR FORCE PROJECTIONS BY
CENTER FOR BUSINESS AND ECONOMIC RESEARCH
AND DEPARTMENT OF EMPLOYMENT SECURITY

	1975 Projected Total Labor Force

Region 8	73,058	64,566	8,492	13.1
Region 9	363,532	362,690	842	0.2

Sources: CBER Labor Force totals are derived from Table 5.2. The 1970 ratio of TDES employment and the Census of Population labor force total was utilized to correct for differences in definition. Projected labor force was adjusted to the TDES definition of employment. That series reports civilian jobs (including multiple job holders) by place of work and excludes employment.

TDES Labor Force totals are from unpublished employment projections of the Research Division, Department of Employment Security, State of Tennessee.

Projected Labor Force Trends

Examination of Table 5.2 indicates that the labor force trends reviewed earlier in this section will continue through 1980. In the 1975 labor force projections, the male labor force for the State of Tennessee

grew from 956,144 in 1970 to 997,344 in 1975, representing a 4.3 percent increase. The female labor force revealed a greater growth rate, 12.4 percent, with 669,323 employed women projected in 1975. The total labor force participation rate in 1975 would be 70.4 for males and 41.9 for females.

It should be noted that four non-metropolitan regions (regions 4, 6, 7, and 8) show an absolute loss in labor force size for males from 1970 to 1975. These losses are due principally to population losses in these regions caused by relatively high outmigration in the middle age categories. The largest growth in total labor force in 1975, both for males and females, is projected to be in the five metropolitan regions; the Bristol, Johnson City, Kingsport area is likely to be recognized by the Office of Management and Budget as a Standard Metropolitan Statistical Area in late 1972.

The labor force projections for 1980 reveal a diminishing disparity between male and female labor force growth rates, as the male labor force in the state is projected to increase by 4.7 percent from 1975 to 1980, while the female labor force would grow by 5.1 percent, a difference of only 0.4 percentage points. In 1980, only Region 7 registers a loss in male labor force size from 1975. As was projected for the 1970 to 1975 period, the metropolitan regions would experience the largest labor force growth from 1975 to 1980.
