General Information

Research and Education Center Tests: The 2008 variety performance tests were conducted on 58 soft, red winter wheat varieties in each of the physiographic regions of the state. Tests were conducted at East TN (Knoxville), Plateau (Crossville), Highland Rim (Springfield), Middle TN (Spring Hill), Milan (Milan), and West TN (Jackson) Research and Education Centers.

All varieties were seeded at rates from 26 - 32 seed per square foot (Table 1). Plots were seeded with drills using 7–7.5 inch row spacings. The plot size was six, seven or ten rows, 22 to 30 feet in length depending on location equipment. Plots were replicated three times at each location. Seed of all varieties were treated with a fungicide.

County Standard Tests: The County Standard Wheat Test was conducted on 19 soft red winter wheat varieties at 10 locations across nine counties in West Tennessee (Dyer, Franklin, Gibson, Haywood, Henry, Lake, Madison, Moore, and Weakley) and one county in western Kentucky (Ballard). Each variety was evaluated in a large strip-plot at each location, thus each county test was considered as one replication of the test in calculating the overall average yield and in conducting the statistical analysis to determine significant differences. At each location, plots were planted, sprayed, fertilized, and harvested with the equipment used by the cooperating producer in his farming operation. The width and length of strip-plots were different in each county; however, within a location in a county, the strips were trimmed on the ends so that the lengths were the same for each variety, or if the lengths were different then the harvested length was measured for each variety and appropriate harvested area adjustments were made to determine the yield per acre.

Insecticide Seed Treatments: In order to evaluate the effects of seed that had been treated with a systemic insecticide such as Cruiser versus seed that had not been treated, five varieties were evaluated in the Research and Education Center tests in 2008. Delta King DK9577, FFR 8302, Pioneer 26R22, USG 3350, and USG 3342 were planted at each location with and without the systemic insecticide 'Cruiser' seed treatment. All plot seed were treated with a fungicide.

Growing Season: The growing season began with fairly normal conditions during the fall planting season across much of the state. The winter temperatures were reasonably moderate with some freezing damage to the plants at some locations. According to the Tennessee Agricultural Statistics Service (TASS), the crop tolerated the winter in good shape with 80% of the crop rated good to excellent in the spring. Three quarters of the crop experienced some insect or disease damage during the season. Hot and dry conditions in late June aided in a harvest slightly ahead of normal. Tennessee producers planted approximately 620,000 acres of wheat in the fall of 2007. Approximately 490,000 acres were harvested for grain in 2008 which is nearly double the 2007 harvested acreage of 260,000. According to the Tennessee Agricultural Statistics Service, the predicted state average yield of 65 bu/a in 2008, if realized, will be the highest state average wheat yields since records began in 1866.

Interpretation of Data

The tables on the following pages have been prepared with the entries listed in order of performance, the highest-yielding entry being listed first. All yields presented have been

adjusted to 13.5% moisture. At the bottom of the tables, **LSD** values stand for **Least Significant Difference**. The mean yields of any two varieties being compared must differ by at least the LSD amount shown to be considered different in yielding ability at the 5% level of probability of significance. For example, given that the LSD for a test is 8.0 bu/a and the mean yield of Variety A was 50 bu/a and the mean yield of Variety B was 55 bu/a, then the two varieties are not statistically different in yield because the difference of 5 bu/a is less than the minimum of 8 bu/a required for them to be significant. Similarly, if the average yield of Variety C was 63 bu/a then it is significantly higher yielding than both Variety B ($63 - 55 = 8 \text{ bu/a} = \text{LSD of } 8$) and Variety A ($63 - 50 = 13 \text{ bu/a} > \text{LSD of } 8$).

Also, the **coefficient of variation (C.V.)** values are shown at the bottom of each table. This value is a measure of the error variability found within each experiment. It is the percentage that the square root of error mean square is of the overall test mean yield at that location. For example, a C.V. of 10% indicates that the size of the error variation is about 10% of the size of the test mean. Similarly, a C.V. of 30% indicates that the size of the error variation is nearly one-third as large as the test mean. A goal in conducting each yield test is to keep the C.V. as low as possible, preferably below 20%.

----- Wheat -----

Results

Yield and Agronomic Traits: During 2008, 58 wheat varieties were evaluated in six research and education center (REC) tests, and 19 varieties were evaluated in 10 county standard tests (CST). Nineteen of the varieties were common to both the REC and the county tests (Table 5). Ten companies and five universities entered varieties into the tests this year. The average yield of the 53 non-insecticide treated varieties in the 2008 REC tests was 62 bu/a (range from 52 to 71 bu/a, Table 2). The average yield of the five insecticide treated varieties in the REC tests was 69 bu/a with individual varieties ranging from 65 to 70 bu/a. The varieties ranged in maturity from 228 to 232 days after planting (DAP) with most of the varieties clustering around 230. The test weight values ranged from 54.3 to 58.7 lbs/bu (Table 3). The average yield of the 19 varieties in the county tests was 76.7 bu/a with individual varieties ranging from 72.5 to 82.3 bu/a. The test weight values ranged from 54.8 to 59.0 lbs/bu (Table 4).

A severe hail storm occurred at the East TN REC (Knoxville) location on May 9, 2008 and caused considerable head lodging in the wheat plots. Approximately 10% of the heads were bent but not broken off of the plants and very little shattering loss of seed occurred.

Due to the severe freeze that occurred in early April 2007 and the atypical yields that were obtained, the data from 2007 are not included in the 2- and 3-year summaries. Instead the 2006 and 2005 data are included for the 2- and 3-year summaries. Thirty-one of the 58 varieties have been evaluated over the two year period (2006 & 2008) and 21 of the 58 have been evaluated for the three year period (2005, 2006, & 2008).

Cruiser Seed Treatments: The Cruiser insecticide seed treatments resulted in fairly consistent yield increases among varieties and REC locations. There were statistically significant yield increases for three of the five varieties (Pioneer 26R22, USG 3342, and USG 3350) that had been treated with Cruiser as compared to the non-Cruiser treated seed across locations. The five varieties treated with Cruiser averaged a statistically significant 5 bu/a

increase across all locations as compared to the non-Cruiser treated seed. (Table 10). This differs from the rather inconsistent responses obtained in previous year's studies of systemic insecticide treated seed in this program. This may be due to increased insect and disease pressure noted by growers across the state and reported by the Tennessee Agricultural Statistics Service this season.

Table 1. Location information from research and education centers where the wheat variety tests were conducted in 2008.

† Yields have been adjusted to 13.5% moisture. Each variety was evaluated in a large strip-plot at each location, thus each county test was considered as one replication of the test in calculating the average yield and in conducting the statistical analysis to determine significant differences (MS).

‡ Official test weight of No. 2 wheat = 58 lbs/bu. - average of 8 locations

MS = Varieties that have any MS letter in common are not statistically different in yield at the 5% level of probability.

Varieties denoted with an asterisk (*), (**), (***) or (****) were in the top performing group in 2007, 2006, 2005 and/or 2004, respectively.

(Yields from freeze damaged 2007 crop not used to qualify for asterisk)

WTREC = West Tennessee Research and Education Center, Jackson, TN.

Data provided by Robert C. Williams, Ext. Area Specialist, Grain Crops, and extension agents in counties shown above.

§ Planting date

Barley

Results

Three released varieties of barley were tested during 2008 at six Research and Education Centers (REC) representing the different physiographic regions of Tennessee. All of the varieties evaluated in these tests were developed in the Barley Breeding Program at Virginia Tech. The variety Eve is a hull-less type and was duplicated in the test with the addition of the systemic insecticide seed treatment Cruiser. A severe hail storm occurred at the Knoxville location on May 9, 2008 and completely destroyed the barley plots.

The average yield of the four entries across the five 2008 harvested locations was 83 bu/a, with a range from 67 to 104 bu/a. The highest yields were obtained at Crossville where the location mean of the four entries was 110 bu/a and the highest variety yield was 138 bu/a (Thoroughbred). The maturity of the barley entries clustered around 228 DAP. The barley varieties adapted to Tennessee generally mature about a week to ten days earlier than adapted wheat varieties. The test weights of the barley entries ranged from 45.1 to 56.1 lbs/bu. Eve has higher test weights due to the hull-less nature of the grain. The official test weight for barley is 48 lbs/bu compared to 58 lbs/bu for wheat.

The Cruiser treated entry (Eve) yielded 7 bu/a more than the non-Cruiser treated entry. Although this yield increase was not statistically significant, it does follow the same trend observed in the wheat tests this season.

Due to the severe freeze that occurred in early April 2007 and the atypical yields that were obtained, the data from 2007 are not included in the 2- and 3-year summaries. Instead the 2006 and 2005 data are included for the 2- and 3-year summaries.

----- Oats -----

Results

A fall seeded oat test was conducted at the East Tennessee Research and Education Center (Knoxville) during 2007-2008 on 25 winter oat varieties / breeding lines. The test was seeded on October 29, 2007. Other experimental details are given in the footnotes of Table 23.

The average yield of the 25 oat entries was 65.4 bu/a, ranging from 37.6 to 98 bu/a. Test weights ranged from 28.9 to 36.1 lbs/bu. The official test weight for oats is 36 lbs/bu. A substantial amount of cold damage occurred on two of the breeding lines from Florida and Louisiana (FL99084-J2 and LA9911SBSBSB-45-B-S-B-S2). A severe hail storm occurred at the Knoxville location on May 9, 2008, resulting in considerable head breakage in the oat plots. This damage was noted and appears in Table 23.

† All yields are adjusted to 14% moisture.

§ Official test weight of Oats = 36 lbs/bu.

Planted 10/29/08
Seeding rate of 22 seed per square foot used for seeding due to shortage of seed supplied

2.46 tons/ac Dolomitic lime applied 9/11/07
263 lbs/ac 10-10-10 applied on 10/3/07, 60 lbs N/ac (34-0-0) applied 3/3/08

Gramoxone @ 32 oz burndown
Harmony Extra XP (0.4oz/ac) applied on 3/13/08

Winter kill notes taken on 2/28/08
Vigor notes taken on 3/13/08 (1=excellent vigor, 5=poor vigor)

Lodging = 1 to 5 scale; where 1 = 95% of plants erect; 2.5 = ~50% of plants leaning at angle ≥ 45°; 5 = 95+% of plants leaning at an angle ≥ 45°.

Hail damage occurred on 5/9/08 which resulted in some head lodging (bent over but not broken off)

Harvested 6/16/08

Table 24. Contact information for wheat and barley seed companies evaluated in yield tests in Tennessee during 2007-8.
