</table>
Complete Conchoidal platform bearing flakes recovered from the screen bags (N244 E140) from the Clovis Deposits.
A34-2

Complete Conchoidal platform bearing flakes recovered from the screen bags from the Pleistocene Sands pre Clovis deposits. Artifacts from units N242 E140, N242 E142, N244 E140, and N244 E142 (97.45-97.15M).
A34-3
Complete Conchoidal platform bearing flakes from the Pleistocene Terrace.
A34-4
Bend Break from the Clovis screen bag. This example likely formed from a snapped flake fragment. Artifact from unit N244 E142.

APPENDIX 37

RESULTS OF MICROWEAR ANALYSIS: ARTIFACT PHOTOGRAPHS AND PHOTOMICROGRAPHS
Appendix A37-1
Results of prior edge-wear analysis. Edge damage and use-wear identified on Bend break graver spur from Pleistocene Terrace at Topper Site (38AL23). (Images courtesy of Albert C. Goodyear and Jim Wiederhold).
Appendix A37-2
Results of 2007 use-wear analysis showing micro-flaked edge on bend break MK20 at magnification 20x. Microscopic image courtesy of Albert C. Goodyear.
Appendix A37-3
Results of use-wear analysis showing micro-flaked edge on Utilized Flake MK06 at magnification 20x. Microscopic image courtesy of Albert C. Goodyear.
Appendix A37-4
Photomicrograph showing feather termination retouch scars on a utilized flake from the Pleistocene Sands at the Topper Site (38AL23).
Appendix A37-5A
Microwear on chert bend break from the Pleistocene Sands. The “greasy” Polish on the surface of this bend break is evidence of cultural activity.

Appendix A37-5B
Microwear on chert bend break from Debra L. Friedkin Site (Left) and bend break from Topper Site (Right). (Image adapted from Weiderhold and Pevny 2014).
Appendix A37-6

Microwear on chert scraper from the Pleistocene Sands. The “bright Polish on the surface of this scraper is evidence of working soft materials such as plants or soft wood.
Appendix A37-7
Residue on distal terminus at left end of chert object at Top. Residue is visible in black in photomicrograph below. The residue on this object is likely due to natural processes.

APPENDIX 39

RESULTS OF EXPERIMENTAL WEATHERING SIMULATION
The chert outcrops at Topper are not impervious to the effects of natural weathering and such processes could explain the occurrence of items misclassified as flakes and flake debris. Specifically, the identification of high quantities of Amorphous debris from the Pleistocene Terrace at Topper warrants further analysis to determine if these materials reflect deposits associated with the technological reductive trajectory implicit in the production of bend breaks or other chipped stone tools, or if such materials were produced naturally. Although chert is tough and has no preferred direction of cleavage, extreme temperature changes may induce artificial cleavage. In some cases, the interior surface of detached pieces may retain distinct markings that resemble compression rings. These “lines” form as the detachment breaks away from the parent cobble and are not as uniform and concentric as compression rings formed via conchoidal flaking. Figure 8-1 presents an example of a chert cobble that exhibits features characteristic of natural formation processes. Likewise, fire can result in the pitting and crazing of the surfaces of chert materials, and such markers can resemble the products of chert cobble testing. As a result, it is important to differentiate between each of these processes and the subsequent byproducts that can form from each. The Figures and tables below present the results of an experimental weathering simulation to evaluate whether lithic detachments can form as the byproducts of specific weathering processes. Where detachments were produced, their attributes were recorded and compared to the attributes of lithic items recovered from the archaeological contexts at the Topper Site (38AL23). Figures A39-1-3 show the change in weight for each cycle of a given weathering simulation. Cobbles tend to increase in weight during wetting cycles and decrease in weight during freezing and thawing cycles.
Chert cobble (1) selected for freeze thaw simulation prior to undergoing experimental weathering. Black and grey lines shows linear trend in weight as simulation study progresses. Freezing has the greater influence on weight decrease than the thawing process.

Chert cobble (2) selected for freeze thaw soak simulation prior to undergoing experimental weathering. There is a decrease in cobble weight as a result of each of the three weathering procedures. (Red line indicates freezing cycle, blue line indicates thawing cycle, and green line indicates wetting cycle).
Figure A39-2B

Mean metric attributes for variables of Bend break length and width (mm) for the Control, Experimental, and Topper assemblages.
Figures A39-6-13 show the results of a study comparing the morphological attributes of pre-Clovis bend breaks and flakes from the Topper Site and lithic items recovered from an off-site control sample.

**Attribute Ratio Analysis**

To evaluate the prospect that the Topper bend break assemblage is morphologically comparable to the control sample, all bend breaks from each of the three samples (Topper, experimental, control) were compared according to the ratio attributes of artifact length/width, width/thickness, thickness/weight and length/weight. The results of this analysis are presented as scatterplots in Figures A39-6-7. The results are indicated as follows:

- For the ratio of bend break length to width, the experimental and Topper assemblages were found to have a high linear correlation as indicated by the $r^2$ values, whereas only a moderate linear correlation was found for the off-site control assemblage. Based on the scatterplot, it is clear that at Topper, as bend break lengths increase, widths also increase.

- For the ratio of bend break width to thickness, only the experimental assemblage was found to show a positive correlation. No positive correlation was found for the Topper or control sample. In fact, the ratio of artifact width to thickness is weak for the Topper and control assemblages.

- Figure A39-6-7 shows the ratios of bend break weight to attributes of length and thickness. According to the scatter plots, all three assemblages display a moderate to positive linear correlation with regard to the ratio of artifact length to weight. By contrast, only the
Topper assemblage was found to exhibit a positive linear correlation when the ratio of artifact weight to thickness measures were examined.

Figure A39-9
Mean metric attributes for variables of flake thickness and weight for the Control, Experimental, and Topper assemblages.
Figure A39-10
Bar chart showing the average number of removal scars on flakes from each assemblage (at top) and average number of retouch segments on flakes from each assemblage (at bottom). Attributes characteristic of retouch were absent on flakes from the Experimental assemblage.
Bar chart showing the average number of retouch segments on bend breaks from each assemblage (at bottom). Attributes characteristic of retouch were absent on the bend breaks from the Experimental assemblage.
Mean attribute scores for each artifact type for artifact exterior surface (x-axis) by interior surface (y-axis) attributes. In the Figure, the quadrants to the right indicate high exterior surface attribute scores based on the attribute scoring analysis whereas the two quadrants at the top of the figure indicate high interior surface values. Based on these results, only the Topper flake category has high interior surface attribute scores, whereas Topper pre Clovis flake and bend breaks have high exterior surface scores.
Figure A39-13
Mean artifact attribute score per assemblage (x-axis) by the percentage of attribute states per assemblage (y-axis). The percentage of items classified by attribute score. According to the graph, peak percentages of the Topper bend break and flake categories have higher attribute scores than the peak percentages of objects from the control sample. Consequently the three samples reflect three distinct assemblages distinguished by mean attribute score.
Scoring system Analysis

Lubinski et al. (2014) have developed a scoring system to distinguish materials modified by humans (artifacts) from natural objects (Lubinski et al. 2014:314). In the method, attributes are given a value of 1 or 0 depending on whether they do (1) or do not (0) meet the criteria of chipped stone tool manufacture. The cumulative attribute values are summed creating an attribute score for the given piece. Items with higher attribute scores are more likely to have resulted from chipped stone tool production whereas items with lower scores are more likely to have formed under natural conditions. For the purpose of this study, the analysis is employed to test the degree of similarity or dissimilarity between the Topper bend break (n=287), Topper flake (n=568), and control (n=69) assemblages. Attributes selected for inclusion in the scoring system for the present study are presented in Table A39-22 and are further distinguished and categorized as belonging to the exterior (5) or interior (5) surface of the piece. Attribute states with a 1 indicate culturally suggestive conditions whereas those with a value of 0 reflect natural conditions. The total maximum score is 10 for artifacts that score a 1 on all 5 exterior and interior attribute conditions. The strongest case for cultural origin would seem to be specimens with high quantities of culturally suggestive attributes whereas items with few such attributes would be those more likely to be of natural origin (Lubinski et al. 2014).

The results of the analysis are presented in Table A39-23. The Topper bend break assemblage has a mean attribute score of 1.94 (of 5) for attributes of the exterior surface and a mean attribute score of 1.1 for attributes of the ventral surface. The interior surface attributes with the highest percentages of positive scores on these items include fissures (44%), compression rings (31.2%), and intact margins (24.3%). By contrast only 4.8% of the Topper bend breaks were found to have a bulb of force and only 6.2% exhibit a striking platform.
When the attributes of the exterior surfaces of bend breaks was considered, the results show that the absence of cortex (86.1%), presence of more than two removal scars (55.2%), and modification retouch (23.9) are the attributes with the highest percentage of positive scores. Items with two or more unidirectional removal scars and feathered terminations occur with less frequency. Interestingly, the presence of differentially weathered removal scars was not observed on possible bend breaks from the Topper sample.

Next, the attribute scores for the control sample were tabulated. The results show a lower mean attribute score for the off-site assemblage. For example, the assemblage has a mean attribute score of 1.27 for the exterior surface attributes and a mean value of .05 for the attributes of the interior surface. Attribute types with the highest percentages of positive scores for the exterior surface category include scar directionality (52%) and scar count (34.7%). Only 28% of bend breaks from the control sample are completely interior and 22% exhibit scars that could be considered possible retouch. Of the items with two or more observable removal scars (n=20), 14 (70%) were found to have differentially weathered scar surfaces on the object exterior indicating that the detachments scars were likely formed at different periods in the lithic objects history.

For the attributes of the interior surface, only a single attribute state (Fissures) has a positive score that occurs on more than one item.

All items classified as flakes from the pre Clovis deposits at Topper were subjected to the attribute score analysis. The results provide a higher mean score value for both exterior (2.25) and interior (3.44) surface conditions when compared to the Topper bend break and control samples. The flake assemblage has higher percentages of items with striking platforms bulbs of percussion, and removal scars than either the Topper bend break or control sample. To illustrate the differences for each assemblage, the mean score value for exterior surface attributes is
presented in Figure A39-12. In the Figure, the quadrants to the right indicate high exterior surface scores whereas the two quadrants at the top of the figure indicate high interior surface values. Based on these results, only the Topper flake category has high interior surface attribute scores, whereas Topper pre Clovis flake and bend breaks have high exterior surface scores.

A second illustration (Figure A39-13) displays the percentage of items classified by attribute score. According to the graph, peak percentages of the Topper bend break and flake categories have higher attribute scores than the peak percentages of objects from the control sample. Consequently the three samples reflect three distinct assemblages distinguished by mean attribute score. The control assemblage has the greatest percentage of lithic objects with scores of 1 or fewer (58%) whereas roughly 1/3rd of the pre Clovis Topper bend break have scores of 2-3, and 1/3rd of the Topper flakes have scores of 6. Whereas the distribution of items from the control sample exhibit an asymmetrical distribution, the Topper flake and bend break assemblages appear unimodal in form. Lubinski (et al. 2014:317) found similar distributions when comparing items from natural matrix to two experimentally flint knapped assemblages.

Although the possible Topper bend break assemblage does have a mean score count more consistent with the control sample as is evident in Figure A39-13, it is more similar to the Topper flake assemblage in three ways. First, both the Topper bend break and flake assemblages have more exterior surface attributes (e.g. absence of cortex, number of removal scars) in common. Second, they have higher incidences of retouch modification suggestive of cultural behavior. Third, the bend breaks from Topper do not exhibit removal scar patterns that are differentially weathered. Taking these results into consideration the Topper bend breaks are more likely to be artifices than geofacts, having greater similarity to artifacts with attributes that are known to occur as the product of human agency.

APPENDIX 41

RESULTS OF CORTICAL ANALYSIS
Figure A 41 -1
Distribution of cortical, quartz and flake weights (g) by depth from unit N242 E130 Pleistocene Sands.
Figure A 41-2
A: Distribution of cortical, quartz, and flake weights by depth from unit N263 E145 Pleistocene Sands. B: Distribution of flakes by depth.
Figure A 42–3
A: Distribution of cortical, quartz, and flake weights by depth from unit N242 E138 NE. B; Distribution of flakes by depth.
Figure A 41–4
A: Distribution of cortical, quartz, and flake weights by depth from unit N242 E140 SE. B; Distribution of flakes by depth.
Figure A 41–5
A: Distribution of cortical, quartz, and flake weights by depth from unit N242 E140 SW. B; Distribution of flakes by depth.
Figure A 41 -6
A: Distribution of cortical, quartz, and flake weights by depth from Unit N242 E142 SW. B; Distribution of flakes by depth.
Figure A 41–7

A: Distribution of cortical, quartz, and flake weights by depth from unit N242 E142 NW. B; Distribution of flakes by depth.
Figure A 41–8
A: Distribution of cortical, quartz, and flake weights by depth from unit N244 E138 SE. B; Distribution of flakes by depth. Entire profile for this quad is Terrace.
Figure A 41–9
A: Distribution of cortical, quartz, and flake weights by depth from unit N246 E138 SE.
B: Distribution of flakes by depth.
Figure A 41–10
A: Distribution of cortical, quartz, and flake weights by depth from unit N246 E138 SW. B: Distribution of flakes by depth
Figure A 41–11
A: Distribution of cortical, quartz, and flake weights by depth from unit N246 E140 SE. B; Distribution of flakes by depth.
Figure A 41–12
A: Distribution of cortical, quartz, and flake weights by depth from unit N246 E140 NE. B; Distribution of flakes by depth.
Figure A41–13
A: Distribution of cortical, quartz, and flake weights by depth from unit N246 E140 NW. B; Distribution of flakes by depth.
Figure A 41–14
A: Distribution of cortical, quartz, and flake weights by depth from unit N248 E140 SE. B: Distribution of flakes by depth.
Figure A41–15
A: Distribution of cortical, quartz, and flake weights by depth from unit N248 E140 SW. B: Distribution of flakes by depth
Results of Pearson's Correlation Test. A; Negative correlation for flake weights by quartz weights from Clovis deposits. B; weak positive correlation for flake weights by cortical weights from Clovis deposits.

\[ r = -0.1423 \]

\[ r = 0.4340 \]

Figure A41–16

Results of Pearson's Correlation Test. A; Negative correlation for flake weights by quartz weights from Clovis deposits. B; weak positive correlation for flake weights by cortical weights from Clovis deposits.
Figure A 41–17
Distribution of river cortex by stratum for units N242 E130, N242 E140, and N246 E140. There is an abrupt decrease in the number of flakes that exhibit river cortex below the Clovis contexts at Topper.
Stratigraphic position of quartz pebbles from the Pleistocene Sands. These quartz lenses presumably resulted from flooding episodes of the Savannah River when it flowed as a braided pattern during the Late Pleistocene. Lithic debitage are found in association with these lenses (97.60m) as well as from the terrace surface below (97.40m) where the quartz lenses are absent.
Figure 41–19

Distribution of quartz pebbles and chert flakes by weight for Unit N246E140 NE. High concentrations of quartz pebbles occur in levels ranging from 97.55m–97.75m. By contrast, the highest concentrations of flakes by weight occur in levels below 97.50m.

Clovis deposits showing the distribution of flakes and quartz pebbles by weight.

Upper Pleistocene Sands deposits showing elevated concentrations of quartz pebbles by weight and low concentrations of flakes by weight.

Lower Pleistocene Sands deposits showing decrease in quartz by weight relative to comparatively higher proportion of flake weight.
Figure 41–20
Illustration showing A; the average weight of quartz pebbles per level for all units examined, B; the average flake weight per level for all units examined, C; Comparison of average quartz weight by average flake weight (x2k) per level. Highest average flake weights for Pleistocene Sands do not overlap with highest average quartz weights. Arrows indicate highest average quartz and flake weights below Clovis respectively.
Figure 41–21
Average flake count by level for all flakes and debitage recovered from the Holocene and Pleistocene Sands.
Results of Pearson's Correlation Test. 

A: Weak positive correlation for flake weights by quartz weights from Pleistocene Sands. 

B: Weak positive correlation for flake weights by cortical weights from Pleistocene Sands.

A

\[ r = 0.3573 \]

B

\[ r = 0.3535 \]

Figure A41-22

Results of Pearson's Correlation Test. A: Weak positive correlation for flake weights by quartz weights from Pleistocene Sands. B: Weak positive correlation for flake weights by cortical weights from Pleistocene Sands.
Figure A41–23
Average number of river stained and thermally altered flakes by level at the Topper Site (38AL23). Dark red shaded area at right indicates levels with highest average quartz content.
Results of Pearson's Correlation Test. 

**A:** Positive correlation for flake weights by quartz weights from Pleistocene Terrace. 

**B:** Positive correlation for flake weights by Cortical weights from Pleistocene Terrace.

$r = .7080$

$r = .6177$
Figure A41–25A
Mean Artifact Weight per level for the Pleistocene Terrace at the Topper Site. Artifacts cluster by weight in three zones. Upper, Middle, and Lower section of the Pleistocene Terrace.
Figure A41–25B
Mean Artifact and Pebble Weight per level for the Pleistocene Terrace at the Topper Site. Artifacts cluster by weight in three zones. Upper, Middle, and Lower section of the Pleistocene Terrace.
Table A41-1
Weight in grams for cortical, quartz and flake materials from unit N242 E130 from 2000 4m x 8m block excavation.

APPENDIX 42

RESULTS OF MASS AND SIZE GRADE ANALYSIS
Figure A 42–1
Distribution of flakes by mean weight per level for each size grade.
Figure A 42–1 continued
Distribution of flakes by mean weight per level for each size grade.
Relationship between flake weight and depth for different stratigraphic units at Topper. The results show a positive correlation in flake weight by depth for Upper Pleistocene Sands and a weak association for the Clovis, Lower Pleistocene Sands and Pleistocene Terrace.

Percentage of flakes by size grade for the upper (blue) and lower (red) Pleistocene Sands. There is a decrease in the amount by weight of smaller flakes with depth. Higher percentages of larger flakes occur in the Lower Pleistocene Sands.
Results of a correlation analysis showing the percentage of flake weight by size grade for the Clovis deposits regressed against the Lower Pleistocene Sands (A), and the Upper Pleistocene Sands regressed against the deposits from the Pleistocene Terrace. There is a moderate positive correlation between the flake assemblage from the Clovis and Lower Pleistocene Sands. By contrast there is a strong positive correlation between the Upper Pleistocene Sands and Pleistocene Terrace; the two assemblages that exhibit the greatest dissimilarity to Clovis.
Results of size grade analysis showing the variation in artifact size by depth for the Clovis, Upper and Lower Pleistocene Sands, and Pleistocene Terrace. The variation in flake size is strongly correlated with depth for the Upper Pleistocene Sands indicating that these deposits were likely subjected to post depositional processes.
Results of a Pearson correlation test showing the linear relationship between large and small flake weights through the stratigraphic profile at Topper. The R value for the Lower Pleistocene Sands indicates an absence of vertical movement of small flakes across this portion of the stratigraphic deposit. (Compare with Figures 9-11 and 9-16 for quartz and cortical pebble distributions).
Figure A 42–7

Distribution of quartz by mean weight per level for each size grade.
Figure A42–7
Distribution of quartz by mean weight per level for each size grade (continued).
Figure A 42–8

Relationship between quartz weight per level and depth for different stratigraphic units at Topper. Results show a weak to moderate positive correlation in quartz weight by depth for all Units sampled. Quartz decreases in abundance with depth throughout the Lower Pleistocene Sands, and increases in abundance for all other stratigraphic units.
Figure A 42–9

Percentage of quartz by size grade for the Clovis (blue), Upper (red) and Lower (green) Pleistocene Sands, and Pleistocene Terrace (purple). There is an increase in the amount by weight of smaller quartz pebbles with depth. The highest percentages of larger quartz only occur at the base of the Pleistocene Terrace.
Results of a Pearson correlation test showing the linear relationship between large and small quartz pebbles through the stratigraphic profile at Topper. The R value for the Pleistocene deposits reflect a moderate positive correlation suggesting a tenancy for high X variables to correlate with high Y variables. R values for the overlying Holocene deposits are lower indicating an absence of correlation in large and small quartz pebbles. Compare with correlation of flakes.

Figure A 42–10
Figure A 42–11
Distribution of cortical pebbles by average weight for 2.5in, 1in, .1/2in, ¼ in. size grades.
Figure A 42–11
Distribution of cortical pebbles by average weight for 1/8in. size grade.
Percentage of cortical pebbles by size grade for the Clovis, Upper and Lower Pleistocene Sands, and Pleistocene Terrace. High percentages of small cortical pebbles occur in the Clovis and Upper Pleistocene Sands.
Figure A 42–13
Relationship between cortical pebble weight and depth for different stratigraphic units at Topper. Results show a weak correlation for the Clovis and Lower Pleistocene Sands deposits, a strong positive correlation for the Upper Pleistocene Sands and a moderate positive correlation for the Pleistocene Terrace. Cortical pebbles decreases in abundance with depth for the Clovis and Lower Pleistocene Sands, and increase for all other stratigraphic units.
Results of a Pearson correlation test showing the linear relationship between large and small cortical pebbles through the stratigraphic profile at Topper. The R value for the Pleistocene Terrace reflects a strong positive correlation suggesting that increases in large pebbles correlate with increases in small pebbles and vice versa.
Figure A42–15
Mean mapped Artifact Weight per level for Pleistocene Terrace.
Table A42–1
Results of the size grade analysis for the flake deposits at Topper showing the average weights for each size grade by level.

APPENDIX 43

SPATIAL ANALYSIS
Appendix 43 presents the results of the Spatial analysis of mapped items from the study sample in addition to other selected excavation areas of the Topper Site. Figures A43–1 through A43–17 illustrate the horizontal spatial distribution of artifacts by type from the study sample. Figures A43–18 through A43–20 and A43–22 through A43–24 illustrate the vertical distribution of artifacts by type from the study sample. Figures A43–25 through A43–27 present the horizontal and vertical distribution of bend breaks and split quartz pebbles by strata followed by the spatial distribution of Taylor points in Figure A43–28. Figure A43–29 offers the spatial distribution of tested cobbles on the Pleistocene Terrace surface as identified by Goodyear and Wilkins (n.d.) followed by the spatial distribution of artifacts by type from the Upper and Lower Pleistocene Sands (Figures A43–30 through.
Figure A43-1
Distribution of all Clovis Artifacts (N=561). NN statistic = .779; p = <.0001.
Figure A43-2
Distribution of all Clovis Bifaces. (n = 77).
Figure A43 - 3
Distribution of all Clovis Flake Tools. (n = 179).
Figure A43-4
Distribution of all Clovis Production Tools. (n=27).
Figure A43 - 5
Distribution of all Clovis Core Tools. (n = 64).
Figure A43 -6
Distribution of all Clovis Bend Break Tools. (n = 9).
Distribution of all pre Clovis mapped items from the Pleistocene Sands. (97.70-97.20m; n=1625).
Distribution of all pre Clovis Bend Break Tools from the Pleistocene Sands. (97.70-97.20 m; n = 65).
Figure A43 -9

Distribution of all pre Clovis Flake Tools recovered from the Pleistocene Sands. (97.70-97.20m; n = 175).
Figure A43 -10
Distribution of all pre Clovis Production Tools recovered from the Pleistocene Sands. (97.70-97.20m; n = 80).
Figure A43 - 11
Distribution of all pre Clovis Core Tools recovered from the Pleistocene Sands. (97.70-97.20m; n = 115).
Figure A43 -12
Distribution of all pre Clovis Non-Tools recovered from the Pleistocene Sands. (97.70-97.20m; n = 256).
Figure A43 -13
Distribution of all pre Clovis Cobbles and Pebbles recovered from the Pleistocene Sands. (97.70-97.20m; n = 671).
Plan view Distribution of Plotted items from the Southern Terrace Excavation (96.70-96.90m). BHT 17 Highlighted. NN statistic = 1.334333; p = 0.00.

Plan View Distribution of Plotted items from the Southern Terrace Excavation (95.95-96.15m). BHT 17 Highlighted. NN statistic = 1.334333; p = 0.00.
Plan View Spatial Distribution of Plotted items from the Southern Terrace Excavation (95.25-95.95m).

Plan View Spatial Distribution of Plotted items from the Northern Terrace Excavation (96.90-96.70m). NN statistic = 1.334333; p = 0.00.
Distribution of all mapped items along the N242 gridline from the 2002-2012 5m x 9m block excavation at the Topper Site (38AL23).

Distribution of all three dimensionally mapped items along the N244 gridline from the 2002-2012 5m x 9m block excavation at the Topper Site (38AL23). Terrace surface is at 97.20m.
Distribution of all mapped items along the N246 gridline from the 2002-2012 5m x 9m block excavation at the Topper Site (38AL23).

Distribution of all mapped items along the N248 gridline from the 2002-2012 5m x 9m block excavation at the Topper Site (38AL23).
Figure A43-21
Plan view map of the distribution of all mapped artifacts from the Clovis (Black) and Pleistocene Sands (Red) deposits from the primary 2002-2012 block excavation.
Figure A43 -22
Profile map showing the distribution of all mapped items from the 2002-2012 5m x 9m block excavation including Pleistocene Terrace deposits (below 97.00m).
Figure A43 - 23
Spatial Distribution of mapped artifacts from the Pleistocene Terrace at the Topper Site (28AL23).
Plan view (top) and profile (bottom) map of the spatial distribution of all mapped artifacts from the 2002-2012 5m x 9m block excavation at the Topper Site (38AL23).
Figure A43 -24B
Profile view of the spatial distribution of mapped artifacts from the 2002-2012 5m x 9m block Holocene and Pleistocene Sands excavation at the Topper Site (38AL23).
Spatial distribution of Clovis bend breaks and split quartz pebbles at the Topper Site (Profile A and Plan view B).
Figure A43-26
Spatial distribution of Pleistocene Sands bend breaks and split quartz pebbles at the Topper Site (Profile A and Plan view B).
Spatial distribution of Pleistocene Terrace bend breaks and split quartz pebbles at the Topper Site (Profile A and Plan view B).

APPENDIX 45

GLOSSARY OF KEY TERMS
**Alluvium:** A term for sediment deposited in a streambed, floodplain or other bottomland feature. An unconsolidated, stratified deposit laid down by water.

**Amorphous Debris:** Lithic specimens that have a discernible interior surface, yet lack compression rings, bulb of force, point of applied force and intact margins.

**Anvil:** A stone or lithic object, typically flat, that is used as a support on which lithic materials to be struck are placed. Anvils are frequently used in the bipolar technique of lithic reduction.

**Archaic:** The period of prehistory in North America that begins approximately 11,700 cal yr. B.P. during the Early Holocene and reflects those cultures who subsist primarily by way of hunting and gathering. The end of the Archaic is defined by the adoption of sedentary farming.

**Argilliturbation:** Mixing in soils or sediments that occur as the result of alternating wetting and drying cycles in clays that shrink and swell.

**Arrises:** Ridges on the exterior surface of a flake that result from the intersection of two or more flake removals.

**Bend Break Flake:** In lithics, a non-conchoidal fracture that is the product of flexing that exceeds the elasticity of the material. According to Andrefsky (2005), the fracture is identified by an absence of a bulb of force, fracture initiation near the center of the artifact’s face, and fracture plane propagation oriented perpendicular to the initiation face. Attributes of bend breaks include compression rings, and radial striations, and lips at the artifact margin.

**Bending Initiation:** In lithic reduction, fracture that occurs when applied pressure of an indentor produces a crack near, but not at the initiation face and develops downward at a 90 degree angle.

**Biface:** A type of lithic artifact that is lenticular in shape that has had flakes removed from two opposing sides or faces of the artifact’s surface. Bifaces are objective pieces that have two sides that converge to create a single margin that circumscribes the entire artifact.

**Biface Thinning Flake:** A percussion flake that has multi-faceted striking platform remnants, that are small and thick, acute platform angles, a curved and thin longitudinal section and cross section, and parallel expanding margins. Biface Thinning Flakes are a product of shaping and thinning a biface.

**Bioturbation:** The physical rearrangement of sediment particles forming the soil and subsoil fabric by disruption through organic or biophysical processes of resident life forms.

**Bipolar Reduction/Manufacture:** A type of lithic reduction whereby a core or objective piece to be flaked is placed on an anvil and subsequently struck with a hammerstone or indenter. Bipolar fractures are initiated wedging and propagate under compressive force. A form of core technology that employs the use of compressive forces to detach a flake from a core.
**Blade:** An elongated lithic detachment with parallel margins, and two or more unidirectional removal scars on its exterior surface.

**Bladelet:** An elongated lithic detachment that is less than 50mm in length and has parallel margins, and two or more unidirectional removal scars on its exterior surface.

**Braided Stream:** A stream with a wide, horizontal channel bed, over which water forms an interlacing pattern of splitting into numerous small conveyances that coalesce a short distance downstream.

**Broken Flake:** Lithic specimens that have a discernible interior surface, compression rings, bulb of force, and a point of applied force, yet lack intact margins.

**Bulb of Force:** An attribute on the interior surface of a conchoidal flake that is positioned towards the proximal end, and below the striking platform remnant. The bulb of force is typically found on flakes detached by way of conchoidal fracture, although its morphology may vary dependent on reductive technique and degree of force application.

**Burin:** A lithic tool flaked into a chisel like point used for inscribing or grooving bone, wood, stone or antler.

**Chert:** A form of sedimentary rock composed of microcrystalline quartz.

**Chopper:** A core tool manufactured by percussion flaking the margins or ends of a cobble or boulder. Choppers are thought to have been used for cutting, crushing, or chopping activities.

**Clay:** A fluvial sediment defined to be of particle diameter no greater than 0.002 mm.

**Clovis Culture:** A prehistoric North American culture complex that first appears in the archaeological record approximately 13,250 cal. years ago. Clovis was first identified near Clovis New Mexico in the 1920’s and 1930’s by the recovery of long, lanceolate, fluted projectile points in recovered association with large extinct megafauna. Clovis is considered to be the ancestors of most indigenous cultures in North America.

**Cobble:** Lithic objects that range in size from 64-256 mm.

**Colluvium:** A a layer, of unconsolidated weathering products deposited following sheet erosion by unconsolidated surface runoff and by gravitational processes, physical weathering, and bioturbation.

**Compression Flake:** Flakes that are a product of wedge initiation whereby the application of force is focused away from the margin of the objective piece, and upon what is considered the center of the hertzian cone.
**Compression Rings**: undulations on the interior surface of a flake and radiate in the direction away from the bulb and point of applied force.

**Complete Flake**: Artifacts that have a single interior surface, compression rings, a bulb of force, a complete or partial striking platform, and intact margins with a clear point of termination.

**Conchoidal fracture**: A breakage in rock that produces concentric circles on the detachment face resulting from pressure or percussion flaking.

**Context**: The exact location of a site, artifact or other discovery in time and space.

**Core**: A Lithic object from which flakes or detachments are removed by some means of reductive technology. The core is also referred to as an objective piece in lithic reduction. Detachments from a core may be used as flake tools or flake blanks.

**Core tool production**: The removal of flakes from an objective piece in either a unidirectional or multidirectional form.

**Cortex**: Natural exterior material surface of stone that is the product of weathering or some other formation process.

**Cortical pebble**: Small sub rounded to angular lithic fragments that were part of the cortex or outer rind of a rock and have subsequently been detached from the parent material, either by weathering or by lithic manufacture.

**Crazing**: Thermal damage on a lithic object or detachment that is is product of differential expansion. Crazing consists of a series of small intersecting cracks in the surface of the lithic object.

**Cryoturbation**: The mixing of sediments from multiple soil horizons as a result of freezing and thawing.

**Datum**: Any point or surface to which other landscape points can be related, either horizontally or vertically, to locate the points on the earth’s surface, usually for purposes of topographic mapping.

**Debitage**: Waste material from the manufacture of chipped stone tools. All stone artifacts of cultural origin that are not cores or tools, a major subset of which are flakes.

**Debris**: Lithic specimens that have a discernible interior surface and compression rings, but lack a bulb of force, point of applied force and intact margins.

**Deposition**: The process of accumulation into beds or irregular masses of loose sediment or other rock material by any natural agent.
**Distal:** An orientation term that denotes the termination end of a flake, detachment, core, or lithic tool.

**Eluviation:** A hydrologic process by which water percolates downward and out of a soil zone, transporting organic material from the surface through the A horizon into the B horizon.

**Eraillure Scar:** An eraillure scar is the negative of a removal flake that separates from the mid-point of the bulb of force as a flake is detached from a nucleus.

**Exterior Surface:** The face of a lithic flake or detachment that corresponds with the outer portion of the artifact from which it was detached. Also referred to as the dorsal surface.

**Faunalturbation:** Modification of soils and sediments caused by animals.

**Flake:** any lithic material detached from a given mass of stone. Complete flakes have a striking platform, bulb of force, intact margins, and compression rings indicative of applied force.

**Flake Class:** In lithic reduction, the position in the reduction sequence to which a particular flake belongs. Flake classes often include primary, secondary or tertiary.

**Flake Fragment:** Lithic specimens that have a discernible interior surface, compression rings, and bulb of force, yet lack a point of applied force and intact margins.

**Flute:** A long, narrow groove resulting from the removal of an elongated channel flake and extending from the basal margin of a projectile point preform or point some distance along the face.

**Fluvial Processes:** The movement of material agents generated by the activities of rivers, streams and associated flow.

**Frost Wedging:** The mechanical weathering of stone induced by stresses created by the freezing of water into ice.

**Graver:** A small tool with a sharp tip used to groove or engrave bone, stone, wood, or other materials.

**Hammerstone:** A lithic percussor or indenter that is used in chipped stone tool production to detach flakes from a core.

**Hard Hammer percussion:** Lithic reduction technique employed with the use of a hard indenter such as a quartzite hammerstone. Hard hammer percussion is often employed during early stages of lithic reduction and results in detachments that are thick and have prominent points of applied force.

**Hertzian Initiation:** In lithic reduction, hertzian initiation occurs when increased loads between an indentor and brittle solid ultimately lead to the formation of cracks in the surface of the solid.
**Hydric Forces:** Forcing mechanisms that influence the structural integrity of stone through the addition or reduction of moisture.

**Illuviation:** The movement of soluble and fine-grained material downward into sites of the B horizon.

**In Situ:** In place.

**Interior Surface:** The face of a lithic flake or detachment that corresponds with the inner portion of the artifact from which it was detached. Also referred to as the ventral surface.

**Interpretation Free Model:** A method of lithic analysis developed by Sullivan and Rozen (1985) that is based on the examination of a set of lithic attribute categories that have three dimensions of variability, each with two possible outcomes. The method is thought to be objective and to enhance replicability.

**Kurtosis:** Peakedness of a grain-size distribution and compares sorting in the central portion of a given population with that in the tails.

**Lithic:** Relating to stone.

**Lithic Analyst:** Those interested in examining stone or chipped stone artifacts to obtain some information about prehistoric life-ways and behavior.

**Lithic Manufacture Technique:** The means by which force is applied during detachment, and includes the implements used, as well as the direction, angle, and amount of applied force.

**Lithic Taphonomy:** The effect that natural processes have on stone materials.

**Lithic technology:** The extensive array of methods employed to manufacture usable tools from a variety of lithic raw material types.

**Margin:** The edge of a flake or tool.

**Mechanical Weathering:** The erosion or breakdown of rock into smaller fragments by natural and physical agents, but without significant change in chemical or mineralogical makeup.

**Medial:** Orientation term that denotes the midsection of a flake, detachment, core or lithic tool.

**Mississippian:** The period of North American prehistory from ca. A.D. 1000 to European contact in the sixteenth century that represents a time of increased social complexity consisting of chiefdom level societies.

**Morphological Attributes:** In Lithic analysis, a term used to describe attributes that define artifact size or shape.
Multidirectional: Core or flake reduction technique with detachments removed in more than one direction or from more than one striking platform.

Non Tool Flakes: Lithic detachments or flakes that do not exhibit evidence of modification, use, or rejuvenation.

Overshot Flake: A flake with a reverse hinge termination that removes part of the core or biface on the opposite margin from which it was initiated.

Palynology: The study of pollen and pollen grains.

Patina: A surface discoloration or adhesive outer crust of an artifact due to chemical changes resulting from weathering.

Pebble: Lithic objects that range in size from 4-64 mm. A general term for a small rock fragment that has been rounded through the process of stream transport.

Pebble/Cobble: Lithic specimens that lack a discernible interior surface, compression rings, bulb of force, point of applied force and intact margins.

Pedogenesis: The mode of origin of a soil, with emphasis on the processes of soil-forming factors responsible for the development of the soil from the unconsolidated parent material.

Percussion Flaking: A lithic reductive technique that produces discriminate interior attributes and remnant percussion scars on the exterior surface of the lithic flake or detachment.

Postdepositional Processes: All natural and anthropogenic processes that have occurred after the deposition of archaeological materials and which could have transformed them into their present state.

Potelid: The scar on a lithic detachment, core, or lithic tool that is formed by thermally induced differential expansion.

Preform: An unfinished flaked tool that reflects a stage in the manufacture process.

Pre Clovis: Term used by archaeologists to refer to Early Paleoindian cultures that are thought to be the founding populations of the Americas.

Pressure Flaking: A lithic reductive technique that uses direct force by pressing as opposed to striking an objective piece, and results in flake detachments that are typically smaller, thinner, and lighter than percussion flakes.

Primary Detachment: A lithic detachment that is entirely covered by cortex on the exterior surface.
**Proximal:** Orientation term that denotes the striking platform or platform remnant end of a lithic detachment, core, or tool.

**Quartz:** Macrocristaline silicate.

**Radial Break:** Fracture caused by the application of force to the midpoint of a flake or tool supported on an anvil.

**Removal Scars:** The negatives of prior flakes or detachments that occur on the exterior surface of a flake.

**River Stained Cortex:** The staining of the outer rind of lithic materials when submerged in or subjected to fluvial activity for an extended period of time.

**Scraper:** A unifacial lithic tool that exhibits use-wear or microwear that is a product of use or rejuvenation. Scrapers are thought to have been used for scraping organic materials such as hide, bone, or grass.

**Secondary Detachment:** A lithic detachment that is partially covered by cortex on the exterior surface.

**Sediment:** Detached fragmental material that originates from either the chemical or physical weathering of rocks and minerals and is transported, suspended in, or deposited by water or air or is accumulated in beds by other natural agencies.

**Sediment Consolidation:** The process(es) by which sediment volume is reduced in response to increased sediment density with natural overburden loading.

**Sheet Flow:** overland flow or downslope movement of water that is not concentrated in channels.

**Site:** A place containing the remains of previous human activity.

**Sorting:** the process by which sediment particles of similar characteristics are selectively separated from other particles.

**Skewness:** the degree of symmetry or asymmetry of a grain-size distribution, which is a function of the mean, median, mode, and kurtosis. A numerical measure or index of the lack of symmetry in a frequency distribution.

**Striking Platform:** The striking platform or point of applied force is the point on a core or objective piece at which a “single flat surface” is struck or hit to remove a detachment.

**Stress Release Weathering:** The release of compressional stresses that are active on a body of lithic material at depth when the weight of overlying sediment is removed by erosion.
**Taphonomy:** The study of geological processes of the transition of animal remains from the biosphere into the lithosphere.

**Thermal Stress:** The strain in a body or structure due to inequalities of temperature. Insolation, natural wildfire, and human-controlled fire features are all conditions that can cause thermal stress.

**Termination:** The end of a flake or core that has been struck during lithic reduction.

**Termination Type:** A set of attribute types that describe the manner in which the distal end of a flake is detached from a nucleus.

**Tertiary Detachment:** A lithic detachment that lacks cortex on the exterior surface.

**Trampling:** The treading, walking, or stepping upon lithic materials by prehistoric peoples or animals.

**Unidirectional:** Core or flake reduction technique with detachments removed in a single direction or from a single striking platform surface.

**Uniface:** A type of lithic artifact that has had flakes removed from a single side or face of the artifacts surface.

**Utilized Flake:** A flake that displays edge modification resulting from use or intentional retouch. Removal scars on utilized flakes extend 2 or more millimeters from the margin of the tool.

**Weathering:** The destruction or alteration, through chemical and biochemical processes, of near-surface rock and sediment.

**Wedging Initiation:** In lithic reduction, initiation that occurs when an indentor strikes an objective piece well away from its margin, or if the edge angle is greater than 90 degrees. Wedging initiation often results in the formation of multiple cracks and fractures from the area surrounding the primary crack and can also occur from the bottom of the objective piece.

**Winnowing:** The preferential transport of fine particles from those of the coarse fraction of a sediment deposit by fluid motion.

**Woodland:** The period of North American prehistory that begins approximately 3,200 cal yr BP and was traditionally distinguished from the preceding Archaic period by the widespread adoption of pottery.
Douglas Sain is an archaeologist specializing in lithic technology and Paleoindian Archaeology. Douglas was born in Boone, North Carolina in 1980. He was raised in North Carolina where he attended Appalachian State University, receiving his Bachelor of Science degree in Anthropology in August, 2003. Douglas received his MA in Anthropology from Eastern New Mexico University in 2011. His thesis research documents Clovis blade technology and technological organization at the Topper Site (38AL23). Douglas received his PhD. in Anthropology in August, 2015 from the University of Tennessee. His dissertation evaluates evidence for pre Clovis lithic technology at the Topper Site. Douglas has worked as an Archaeologist throughout the Southeast U.S. and has worked as a site supervisor at the Topper Site since 2005. His recent publications are focused on Paleoindian settlement subsistence along the southern Atlantic slope of North America and Clovis blade technology in the Central Savannah River Valley of South Carolina.
