Draft Genome Sequences of 10 Strains of the Genus Exiguobacterium

Center for Environmental Biotechnology, University of Tennessee, Knoxville, Tennessee, USA; UT-ORNL Joint Institute for Biological Sciences, Oak Ridge, Tennessee, USA; DOE Joint Genome Institute, Walnut Creek, California, USA

High-quality draft genome sequences were determined for 10 Exiguobacterium strains in order to provide insight into their evolutionary strategies for speciation and environmental adaptation. The selected genomes include psychrotrophic and thermophilic species from a range of habitats, which will allow for a comparison of metabolic pathways and stress response genes.

Exiguobacterium, belonging to the order Bacillales of the phylum Firmicutes, was proposed as a new genus in 1983 by Collins et al. (1) and includes 16 species. All these species are Gram-positive, rod-shaped, facultative anaerobes, motile via peritrichous flagella and have been isolated from a wide range of habitats, with temperatures ranging from −12° to 55°C (2). The ability of individual strains isolated under psychrotrophic or thermophilic conditions to grow in the mesophilic temperature range of 15° to 37°C suggests that Exiguobacterium species have unique and conserved genetic pathways allowing these organisms to exploit a diversity of temperature-related habitats. In addition, species with close affiliation to modern strains have been isolated from permafrost and ice estimated to be >100,000 years old.

The genome sequences were determined for 10 Exiguobacterium strains, including six type strains and four environmental isolates (Table 1). High-molecular-weight genomic DNA was iso-

† Type strains (T) were obtained from the German Collection of Microorganisms and Cell Cultures (DSM) or Japan Collection of Microorganisms (JCM).
lated from strains grown overnight at 30°C in tryptic soy broth using the Joint Genome Institute (JGI) modified cetytrimethylammonium bromide (CTAB) protocol (3). The draft genomes were generated at JGI using Illumina and Pacific Biosciences (PacBio) technologies. Illumina shotgun and long-insert mate-pair libraries were constructed and sequenced using the Illumina HiSeq 2000 platform (4). Filtered Illumina reads were assembled using AllPaths-LG (5). PacBio SMRTbell libraries were constructed and sequenced on the PacBio RS platform, and raw reads were assembled using HGAP version 2.0.1 (6). Genes were identified using Prodigal (7), followed by manual curation using GenePRIMP (8). The predicted coding sequences (CDSs) were translated and used to search the NCBI nonredundant, UniProt, TIGRfam, Famb, KEGG, COG, and InterPro databases. The tRNAscan-SE tool (9) was used to find tRNA genes, and rRNA genes were identified against models of the rRNA genes built from SILVA (10). Noncoding RNAs were found by searching the genomes for the corresponding Rfam profiles using Infernal (11). Gene prediction analysis and manual functional annotation were performed within the Integrated Microbial Genomes (IMG) platform (12).

The Exiguobacterium strains have low G+C contents (average, 48.4%) and vary slightly in their genome size, number of CDSs, and ribosomal RNA (rrn) operons (Table 1). Whole-genome sequencing identified 13 transposase families, which is consistent with those found in previous publications (2, 13). The two most abundant transposase families, transposase/inactivated derivatives and IS605 (orfB), are present in all strains. The strains contain two to seven cold shock protein genes (COG1278), one molecular chaperone GroPE (heat shock protein, COG0576), one ribosome-associated heat shock protein (S4 paralog, COG1188), three chaperonin GroEL (HSP60 family, COG0459), three co-chaperonin GroES (HSP10, COG0234), and four fatty acid desaturase (COG3239) genes per strain.

The presence of multiple genes encoding stress-responsive proteins may explain the broad temperature range for growth and the ability of the Exiguobacterium strains to colonize and thrive in diverse ecological niches.

Nucleotide sequence accession numbers. These whole-genome shotgun projects have been deposited in DDBJ/EMBL/GenBank under accession numbers JNIR00000000, JNIS00000000, JHZV00000000, JMK50000000, JHZS00000000, JHUU00000000, JNIO00000000, JHZT00000000, JNIP00000000, and JPOD00000000. The versions described in this paper are the first versions, JNIR01000000, JNIS01000000, JHZV01000000, JMK50100000, JHZS01000000, JHZU01000000, JNIO01000000, JHZT01000000, JNIP01000000, and JPOD01000000.

ACKNOWLEDGMENTS
This research was performed through the Community Science Program, CSP 2012. The work conducted by the U.S. Department of Energy Joint Genome Institute, a DOE Office of Science User Facility, is supported by the Office of Science of the U.S. Department of Energy under contract DE-AC02-05CH11231.

We thank the Yellowstone National Park Service for coordinating and allowing sampling under permit YELL-1502. We are grateful to J. M. Tiedje, S. Kathariou, R. F. Ramaley, and V. Miteva for providing strains E. undae 190-11, E. sibiricum 7-3, Exiguobacterium sp. NG55, and Exiguobacterium sp. GIC31.
